The IC provides chime service for all available features in the chime warning system, except for the audible warning function provided by each of the optional park assist system display modules. The IC relies on its internal programming, numerous hard-wired inputs, and electronic message inputs received from other modules over the CAN data bus to provide the chime warning system features. The internal programming of the IC determines the priority of each chime request input that is received, as well as the rate and duration of each chime that is to be generated.

The hard wired circuits between components related to the chime warning system may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the chime warning system or the electronic controls and communication between modules and other devices that provide some features of the chime warning system. The most reliable, efficient and accurate means to diagnose the chime warning system or the electronic controls and communication related to chime warning system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

FORWARD COLLISION WARNING

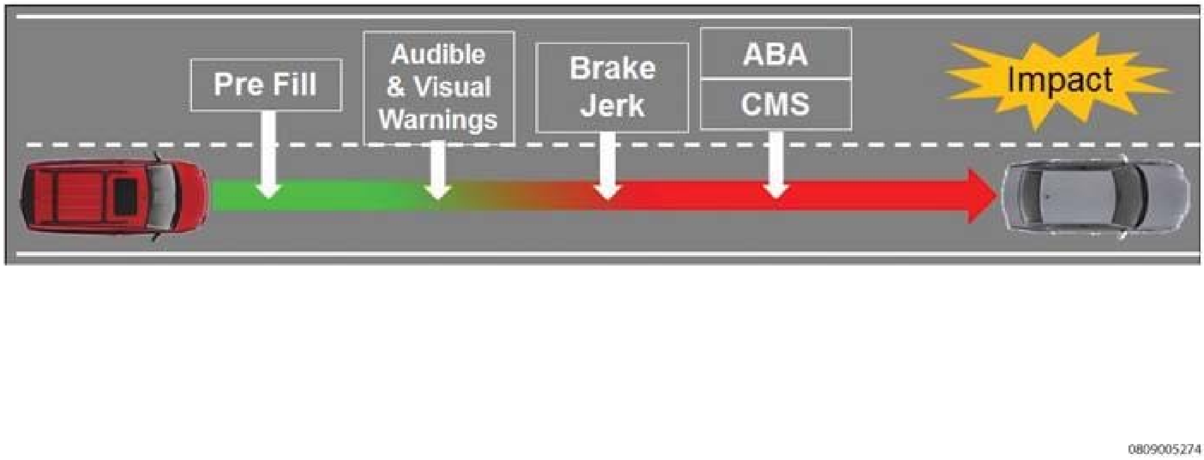
The Forward Collision Warning (FCW) system is only active when the status of the ignition switch is ON and the PRNDL is in D (Drive). The system can be manually disabled and enabled by the vehicle operator using hard button on the Integrated Center Stack (ICS). The default status of FCW is "On". The system state is kept in memory from one key cycle to the next. If the system is turned OFF, it will remain OFF when the vehicle is restarted. The minimum speed for FCW activation is 5 mph (10 km/h).

Components that make up the FCW system are the Powertrain Control Module (PCM), ICS and the Adaptive Cruise Control Plus (ACC) radar sensor/module. The radar module is the component that is responsible for the FCW and ACC decision making process. The radar determines if a FCW or an ACC event needs to occur.

Since there are multiple modules involved in the operation of the FCW system, all faults or diagnostic trouble codes should be checked during diagnosis. The system utilizes the radar sensor in front of the vehicle, so any alignment or configuration issues may cause the system to be inoperative. If the ACC radar detects incorrect or compromised information, the ACC/FCW will function in a limited capacity.

NOTE: **The FCW does not stop the vehicles automatically, but alerts and assists the driver to help avoid or mitigate a collision. If the driver does not respond to any**

of the audible, visual, and haptic warnings, the impact may not be avoided



[Fig. 2: Forward Collision Warning Plus]
Courtesy of CHRYSLER GROUP, LLC

The FCW+ system uses fusion of the sensor data from the ACC radar and the FFC to detect a probable frontal or forward collision. The following actions will be performed when qualified:

- **Pre Fill -** The pre-fill process prepares the brakes for emergency braking by engaging the pump and applying a small amount of pressure to the brakes. This allows for immediate braking. Sufficient pressure applied between the brake pads and the discs means that driver intervention has a more immediate impact.
- **Audible and Visual Warnings -** Audible sounds within the cabin of the vehicle and visual warnings shown within the EVIC are activated when necessary to notify the driver.
- **Brake Jerk -** A short deceleration is performed to alert the driver.
- **Collision Mitigation System (CMS) -** CMS assists braking operation by automatically applying an appropriate amount of braking force to help avoid or minimize the chances of hitting a vehicle. CMS allows up to 1.5 seconds of braking to give the driver additional reaction time. When CMS activates its automatic brake, it also turns the brake lights on.
- **Advanced Brake Assist (ABA) -** Once the driver presses the brake pedal, advanced brake assist (ABA) will engage If the driver is not applying enough force. ABA will increase the braking force required to avoid or mitigate the accident. If the driver does not react to any of the previous warnings, the collision cannot be avoided.

PARK ASSIST SYSTEM

The park assist system is active only when the status of the ignition switch is On, the transmission gear selector is in either the Reverse **R** position and the vehicle speed is less than about 11 kph (7 mph). The system can be manually disabled and enabled by the vehicle operator using the park assist Off push button in the instrument panel center stack switch pod (also known as the Accessory Switch Bank Module/ASBM). In vehicles equipped

with this option, the system is enabled from the factory as a default.

The disable feature is provided for trailer towing purposes or for driver preference. With a trailer attached to the vehicle the audible and visible park assist alerts would be incessant whenever the transmission gear selector was in the Reverse (**R**) position due to the proximity of the trailer to the rear of the vehicle. When the system is disabled, a park assist icon will appear within the display. On vehicles equipped with an optional EVIC, a **PARK ASSIST OFF** textual message will appear within the EVIC display of the instrument cluster whenever the transmission gear selector is in the Reverse **R** position.

The microcontroller-based Park Assist Module (PAM) (also known as the ParkTronic System/PTS module) is the central component of the park assist system. It supplies voltage to the park assist sensors, receives and analyzes data from the sensors, calculates and communicates the proper display information to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC), performs system diagnostics, and communicates with other electronic modules in the vehicle or with a diagnostic scan tool over the Controller Area Network (CAN) data bus. The module operates on battery voltage received through a fuse in the Power Distribution Center (PDC), and is grounded through a take out of the body wire harness.

Four ultrasonic park assist sensors in the rear bumper fascia allow the park assist system to locate and identify the proximity of nearby obstacles. These sensors each generate ultrasonic sound pulses when triggered by the park assist module, then signal the module when an echo of the reflected sound pulses is received. The detection distance range from the rear of the vehicle is about 0.3 meters (11.8 inches) to about 2.0 meters (80 inches), and the detection height range from the ground is about 0.2 meters (7.8 inches) to about 0.8 meters (31 inches). The detection area extends somewhat around both rear sides (corners) of the vehicle.

The park assist display, located within the EVIC unit, provides the vehicle operator with a visible warning if the vehicle comes to within about 100 centimeters (39 inches) to 200 centimeters (79 inches) of the detected object. The display is active any time the vehicle is in Reverse (**R**) and visible to the vehicle operator only when looking forward. When an object is detected within the detection zone, the system will also emit a series of short, intermittent, audible beeps and automatically lower the volume of the audio system 20 dB below a set tone alert volume, if the vehicles audio system is turned On. The audible warning changes from intermittent beeps to a continuous tone as the vehicle comes to within 30 centimeters (12 inches) of a detected object.

When the PAM monitors a problem in any of the park assist system circuits or components, it stores a fault code or Diagnostic Trouble Code (DTC) in its memory circuit. The PAM then sends an electronic message over the CAN data bus, and one of several **SERVICE PARK ASSIST SYSTEM** textual and graphical messages is displayed within the EVIC display when the message is received by the IC.

The hard-wired circuits between components related to the park assist system may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the park assist system or the electronic controls and communication between modules and other devices that provide some features of the park assist system. The most reliable, efficient and accurate means to diagnose the park assist system or the electronic controls and communication related to park assist system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - BLIND SPOT MONITOR SYSTEM

WARNING: To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor, or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.

The following textual messages related to the Blind Spot Monitor (BSM) system may appear within the Electronic Vehicle Information Center (EVIC) display of the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC):

- **BLIND SPOT SYSTEM OFF** - This message to the vehicle operator when the ignition switch first transitions to the On status indicates that the BSM system has been turned Off using the customer programmable features function of the Radio Receiver Module (RRM) (also known as the radio or the head unit).
- **SERVICE BLIND SPOT SYSTEM** - This message to the vehicle operator while the ignition switch status is On indicates that the BSM system is unavailable due to a monitored system fault or faults.
- **BLIND SPOT SYSTEM TEMPORARILY UNAVAILABLE** - This message to the vehicle operator while the ignition switch status is On indicates that the BSM system is temporarily unavailable as a result of one of the following:
    1. **Sensor Blockage** - The amber BSM visual icon in both outside rear view mirrors will be illuminated as long as blockage exists or until the ignition switch status transitions to Off, whichever occurs first.
    2. **Monitored System Fault** - The BSM system has detected a monitored system fault condition and has stored a Diagnostic Trouble Code (DTC). The amber BSM visual icon will be illuminated in both outside rear view mirrors for as long as the condition exists or until the ignition switch status transitions to Off, whichever occurs first.

NOTE: If the BLIND SPOT SYSTEM TEMPORARILY UNAVAILABLE message is received for a minimum of 5 minutes, please verify that the outboard area at each end of the rear fascia behind the rear wheel openings where the radar sensors are located is not blocked by snow, ice or road debris. If the area is blocked, remove the blockage and verify that the message is no longer present in the EVIC display.

NOTE: If the vehicle has experienced any trauma in the outboard area at each end of the rear fascia behind the rear wheel openings where the sensors are located, even if the fascia is not damaged, the radar sensor may have become misaligned. A misaligned radar sensor will result in the BSM system not operating properly.

The hard wired circuits between components related to the BSM system may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the BSM system or the electronic controls and communication between modules and other devices that provide some features of the system. The most reliable, efficient and accurate means to diagnose the BSM system or the electronic controls and communication related to BSM system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

DIAGNOSIS AND TESTING - CHIME WARNING SYSTEM

WARNING: To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.

The hard wired circuits between components related to the chime warning system may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the chime warning system or the electronic controls and communication between modules and other devices that provide some features of the chime warning system. The most reliable, efficient and accurate means to diagnose the chime warning system or the electronic controls and communication related to chime warning system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

DIAGNOSIS AND TESTING - FORWARD COLLISION WARNING

The hard wired circuits between components related to the Forward Collision Warning (FCW) system may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. The wiring information includes wiring diagrams, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the FCW system or the electronic controls and communication between modules and other devices that provide some features of the FCW system. The most reliable, efficient and accurate means to diagnose the FCW system or the electronic controls and communication related to FCW system operation requires the use of a diagnostic scan tool.

DIAGNOSIS AND TESTING - PARK ASSIST SYSTEM

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

NOTE: **The presence of operating heavy construction equipment, large trucks and other vibrations in the vicinity of the vehicle could impact the performance of the system.**

The following textual messages may appear in the Electronic Vehicle Information Center (EVIC):

1. **SERVICE PARK ASSIST** - If a service park assist textual message appears in the EVIC display, the system may or have a hard fault, and further investigation may be needed.
2. **CLEAN PARK ASSIST SENSORS** - If a clean park assist sensors textual message appears in the EVIC display, be certain to confirm the following:
    - The park assist system is self correcting, please verify that the area of the rear bumper where the sensors are located (both the face and the back) is not blocked by ice, snow, mud or other obstructions. If the area is blocked, remove the blockage, shift the transmission gear selector into Reverse (**R**) and verify the message is no longer present in the EVIC display. The system may also be corrected when the vehicle is driven at a speed greater than 14 kph (8 mph).
3. **SERVICE PARK ASSIST SENSORS** - If a service park assist sensors textual message appears in the EVIC display, a sensor or the sensor wiring may be damaged, and further investigation may be needed.
4. **PARK ASSIST OFF** - If a **PARK ASSIST OFF** textual message appears in the EVIC display, the system may have been manually shut Off.

The hard wired circuits between components related to the park assist system may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the park assist system or the electronic controls and communication between modules and other devices that provide some features of the park assist system. Refer to the appropriate diagnostic information.

DISPLAY, BLIND SPOT

DESCRIPTION

DESCRIPTION

Vehicles equipped with the Blind Spot Monitor (BSM) system have a display that appears in both the right and

left outside rear view mirrors. The display consists of a translucent triangle icon in the mirror glass that is illuminated by an amber Light Emitting Diode (LED) unit mounted behind the icon on the mirror glass case. When illuminated, only the amber colored triangle is visible on the outer surface of the mirror glass. The LED unit for the display is connected to the vehicle electrical system along with the other wiring for the power mirror through a dedicated take out and connector of the door wire harness.

The BSM displays are each integral to the outside rear view mirror glass and case unit. The displays cannot be adjusted or repaired. If a BSM display is ineffective or damaged, the entire mirror glass and case unit must be replaced. Refer to **MIRROR, OUTSIDE REARVIEW, REMOVAL** , **MIRROR, OUTSIDE REARVIEW, GLASS, REMOVAL** , **MIRROR, OUTSIDE REARVIEW, INSTALLATION** and **MIRROR, OUTSIDE REARVIEW, GLASS, INSTALLATION** .

OPERATION

OPERATION

The Blind Spot Monitor (BSM) displays provide the vehicle operator with a visual alert that a target vehicle (object of interest) has been detected by the BSM system within one of the BSM or Rear Cross Path (RCP) detection zones. The BSM display is also illuminated momentarily as a bulb test each time the ignition switch status transitions to On as a part of the BSM system self tests. If a BSM display remains illuminated with the automatic transmission gear selector in the Park (**P**) position, it indicates that the BSM system has registered a system fault and may require service.

Each BSM display is completely controlled by a hard wired output of the Driver Door Module (DDM) or Passenger Door Module (PDM) on the same side of the vehicle as the display. The DDM and PDM receive electronic messages over the Controller Area Network (CAN) data bus from the Blind Spot Module (BSM) integral to the RAdio Detection And Ranging (RADAR) smart sensor (also known as Left Blind Spot Sensor/LBSS or Right Blind Spot Sensor) for the same side of the vehicle. The display units are grounded at all times through a takeout and eyelet terminal of the body wire harness that is secured to the body sheet metal.

The hard wired circuits between the BSM displays and the DDM or PDM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the BSM displays or the electronic controls and communication between other modules and devices that provide some features of the BSM displays. DISPLAY, PARK ASSIST

DESCRIPTION

DESCRIPTION

The park assist display is an integral part of the Electronic Vehicle Information Center (EVIC). The park assist graphic is displayed any time the transmission gear selector is in the Reverse (**R**) position. An electronic message is sent to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) from the Park Assist Module (PAM) (also known as the ParkTronic System/PTS module) over the Controller Area Network (CAN) data bus when an object is within the detection area. The IC then displays the corresponding alert bar with the park assist graphic within the EVIC display giving a graphical representation for the distance and location of the object.

Depending upon market and system capabilities, the display graphic has many different variations with three zones (center zone, left corner zone and right corner zone), each with up to six dedicated alert bars. Which graphic is displayed depends upon the size, location and distance of the object being detected.

Only one alert bar is displayed in each zone at any given time. The display graphic will include the furthest alert bar followed by a single tone for maximum distance, then will switch to nearer and nearer alert bars as the proximity to the object is reduced combined with more and more frequent repetitive tones. For minimum distance the nearest bar is displayed and accompanied by a continuous tone output.

The park assist display is only serviced as a complete unit with the EVIC display in the IC. It cannot be adjusted or repaired. If ineffective or damaged, the entire IC unit must be replaced.

OPERATION

OPERATION

The Park Assist system for this vehicle is only available on vehicles equipped with an Electronic Vehicle Information Center (EVIC). The park assist display is an integrated into the EVIC, which receives battery current and ground through and is completely controlled by the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC).

The IC will display a park assist graphic whenever the transmission gear selector is in the Reverse (**R**) position and a signal is received from the Park Assist Module (PAM) (also known as the ParkTronic System/PTS module) over the Controller Area Network (CAN) data bus. The microcontroller within the PAM continually monitors the display status, and will store a Diagnostic Trouble Code (DTC) in memory for any monitored fault detected in the park assist display.

The hard wired circuits between components related to the park assist display may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

MODULE, PARK ASSIST

DESCRIPTION

DESCRIPTION

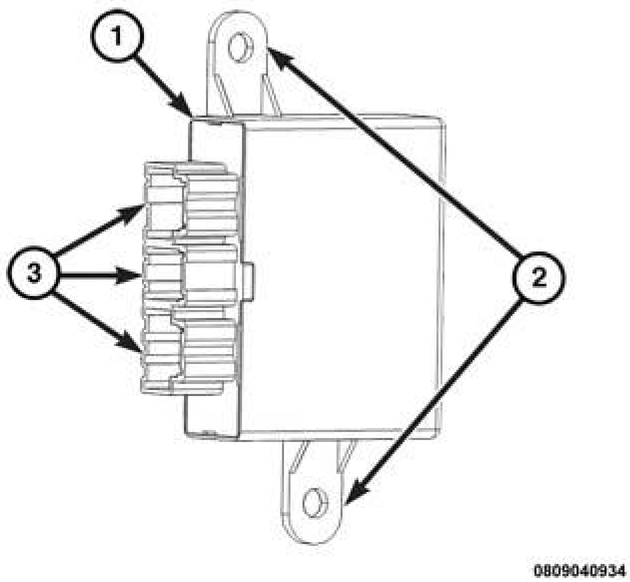

Fig. 3: Park Assist Module, Connector Receptacles & Mounting Tabs
Courtesy of CHRYSLER GROUP, LLC

The Park Assist Module (PAM) (also known as the ParkTronic System/PTS module) (1) is secured to the right inner quarter panel behind the right rear wheel housing in the trunk compartment. One of the two mounting tabs (2) integral to the module housing is inserted into a stamped pocket in the inner quarter panel, while the other mounting tab is secured with a push-in plastic fastener. The module is concealed behind the trunk side trim. Concealed within the molded plastic PAM housing is a microcontroller and the other electronic circuitry of the module. The module housing is sealed to enclose and protect the internal electronic circuitry. The module software is flash programmable.

Three connector receptacles (only two are used for this application) (3) containing terminal pins are integral to the forward-facing side of the housing. The module is connected to the vehicle electrical system through two dedicated take outs and connectors of the body wire harness.

The PAM cannot be adjusted or repaired and, if damaged or ineffective, it must be replaced with a new unit.

OPERATION

OPERATION

The microcontroller within the Park Assist Module (PAM) (also known as the ParkTronic System/PTS module) contains the park assist system logic circuits. The PAM uses On-Board Diagnostics (OBD) and can communicate with other electronic modules in the vehicle as well as with the diagnostic scan tool using the Controller Area Network (CAN) data bus. This method of communication is also used for park assist system diagnosis and testing through the 16-way data link connector located on the driver side lower edge of the

instrument panel.

The PAM provides source current to the four park assist sensors located on the back of the rear bumper fascia. The PAM then monitors return inputs from each of the sensors on dedicated hard wired data communication circuits. These sensor inputs allow the PAM to determine when an obstacle is in the rear path of the vehicle, to calculate the relative location of the obstacle and to determine whether the distance to that obstacle is increasing or decreasing.

Pre-programmed decision algorithms and calibrations allow the PAM microcontroller to determine the appropriate park assist system outputs based upon the inputs received from the park assist sensors and electronic messages received from other modules in the vehicle over the CAN data bus. When the programmed conditions are met, the PAM sends electronic messages to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) and the Radio Receiver Module (RRM) (also known as the radio or the head unit) over the CAN data bus to obtain the proper park assist system visual and audible outputs.

The PAM microcontroller continuously monitors all of the park assist system electrical circuits and components to determine the system readiness. If a monitored system fault is detected, the PAM sets a Diagnostic Trouble Code (DTC) and sends the appropriate electronic messages to the IC to control the display of the appropriate park assist system graphics and textual messages in the Electronic Vehicle Information Center (EVIC) display within the IC and the generation of the appropriate audible warnings by the RRM.

The PAM receives battery current on a fused ignition output (run) circuit through the Body Control Module (BCM). The PAM has a path to ground at all times through a ground circuit and take out of the body wire harness that is secured to the body sheet metal. These connections allow the PAM to be operational whenever the status of the ignition switch is On.

The hard wired circuits between components related to the PAM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the PAM or the electronic controls and communication between modules and other devices that provide some features of the park assist system. The most reliable, efficient and accurate means to diagnose the PAM or the electronic controls and communication related to park assist system operation requires the use of a diagnostic scan tool.

1. Disconnect and isolate the negative cable from the battery. If equipped with an Intelligent Battery Sensor (IBS), disconnect the IBS connector before disconnecting the negative cable from the battery.
2. Remove the trim from the right quarter inner panel to access the Park Assist Module (PAM) (3), which is located just behind the right rear wheel house. Refer to **CARPET, REMOVAL** .
3. Disconnect the body wire harness connectors (1) from the PAM connector receptacles.
4. Remove the push-pin type retainer (2) that secures the PAM to the quarter inner panel.
5. Slide the PAM upward far enough to disengage the lower mounting tab from the stamped pocket (4) in the right quarter inner panel.
6. Remove the PAM from the vehicle.

SENSOR, BLIND SPOT

DESCRIPTION

DESCRIPTION

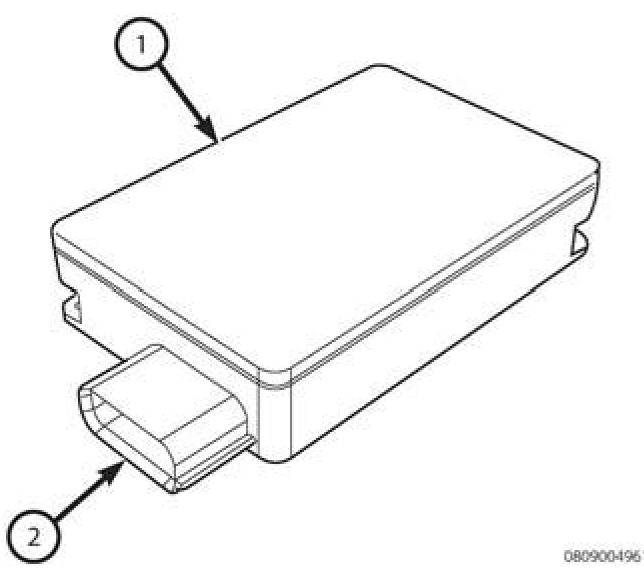

Fig. 6: Blind Spot Sensor
Courtesy of CHRYSLER GROUP, LLC

Vehicles equipped with the optional Blind Spot Monitor (BSM) system have two primary components. These components are the two RAdio Detection And Ranging (RADAR) blind spot sensors (1) (also known as the Left or Right Blind Spot Sensors/LBSS or RBSS). In this vehicle, each sensor also includes an internal microcontroller and control circuitry that monitors and controls both the sensor and the blind spot display for the same side of the vehicle. This explains why the sensors are sometimes referred to as smart sensors.

Each sensor with control circuitry is contained and protected within a molded plastic case that includes an integral connector receptacle (2) at one end. The sensors are each connected to the vehicle electrical system through a dedicated take out and connector of the rear bumper fascia wire harness. The two sensors are concealed behind the outboard ends of the rear bumper fascia. Each sensor is snapped into a dedicated molded plastic mounting bracket that is permanently affixed to the inside surface of the fascia just behind the left and right rear wheel openings.

The blind spot sensors and control circuitry cannot be adjusted or repaired. If a sensor is damaged or ineffective, it must be replaced with a new unit. The sensor module software is flash capable. The mounting bracket for each sensor is serviced only as a unit with the rear bumper fascia.

OPERATION

OPERATION

The Blind Spot Monitor (BSM) RAdio Detection And Ranging (RADAR) smart sensors (also known as the Left Blind Spot Sensor/LBSS and Right Blind Spot Sensor/RBSS) are each controlled by their on-board microcontroller and control circuitry. When the microcontroller recognizes that the appropriate conditions exist, it will energize the sensor to generate 25 Gigahertz radar pulses through the blind spot zone on that side of the vehicle. The sensor receives and filters the radar signals being returned from any objects detected within the zone, then transmits the appropriate data identifying the position and speed of identified objects to the microcontroller.

The microcontroller analyzes the sensor data to determine whether any detected objects should be reported. When it is determined that an object should be reported, the microcontroller sends electronic request messages over the Controller Area Network (CAN) - Interior High Speed (IHS) data bus to its respective Driver Door Module (DDM) or Passenger Door Module (PDM). The DDM or PDM then controls its respective left or right BSM display directly through a hard wired output. The microcontroller of the LBSS or RBSS also sends electronic messages to the Radio Receiver Module (RRM) (also known as the radio or head unit) to mute any current output through the sound system speakers and to generate chime tones as an audible alert.

Each of the two BSM smart sensors is independent and communicates on the CAN data bus. The sensor performs a bulb test by requesting illumination of the triangle icon in its respective right or left blind spot display for a few seconds each time the status of the ignition switch transitions to On. Each sensor microcontroller also continually monitors the BSM system and the sensor circuits and will store a Diagnostic Trouble Code (DTC) for any fault that is detected.

The hard wired circuits between of the smart sensors may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the smart sensors or the electronic controls and communication between other modules and devices that provide some features of the BSM system. The most

reliable, efficient and accurate means to diagnose the smart sensors or the electronic controls and communication related to LBSS or RBSS operation requires the use of a diagnostic scan tool.

Refer to the appropriate SYSTEM WIRING DIAGRAMS article. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the smart sensors or the electronic controls and communication between modules and other devices that provide some features of the BSM system. The most reliable, efficient and accurate means to diagnose the smart sensors or the electronic controls and communication related to LBSS or Right Blind Spot Sensor RBSS operation requires the use of a diagnostic scan tool.

REMOVAL

REMOVAL

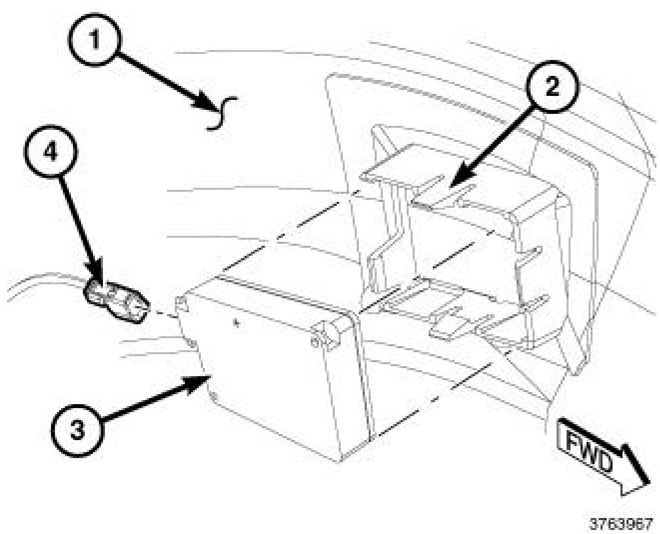

Fig. 7: Blind Spot Sensor, Latch Tabs & Harness Connector

1. Disconnect and isolate the negative cable from the battery. If equipped with an Intelligent Battery Sensor (IBS), disconnect the IBS connector before disconnecting the negative cable from the battery.
2. Remove the rear bumper fascia (1) from the vehicle. Refer to **FASCIA, REAR, REMOVAL** and **FASCIA, REAR, LOWER, REMOVAL** .
3. Disconnect the rear bumper fascia wire harness connector (4) from the Left Blind Spot Sensor (LBSS) or Right Blind Spot Sensor (RBSS) (3) connector receptacle.
4. Disengage the latch tabs (2) of the BSM sensor mounting bracket and pull the LBSS or RBSS out of the bracket.

INSTALLATION

INSTALLATION

NOTE: **Be certain that both the Left Blind Spot Sensor (LBSS) and the Right Blind Spot Sensor (RBSS) part numbers are at the same revision level. The Blind Spot Monitor (BSM) system will not function or will not function properly if the revision levels of the LBSS and the RBSS part numbers are not synchronized.**

1. Position the Left Blind Spot Sensor (LBSS) or Right Blind Spot Sensor (RBSS) (3) to the mounting bracket on the rear bumper fascia (1).
2. Using hand pressure, press the LBSS or RBSS firmly and evenly into the mounting bracket until the latch tabs (2) are fully engaged.
3. Reconnect the rear bumper fascia wire harness connector (4) to the LBSS or RBSS connector receptacle.
4. Reinstall the rear bumper fascia onto the vehicle. Refer to **FASCIA, REAR, INSTALLATION** and **FASCIA, REAR, LOWER, INSTALLATION** .
5. Reconnect the negative cable to the battery. If equipped with an Intelligent Battery Sensor (IBS), reconnect the IBS connector.

SENSOR, PARK ASSIST

DESCRIPTION

DESCRIPTION

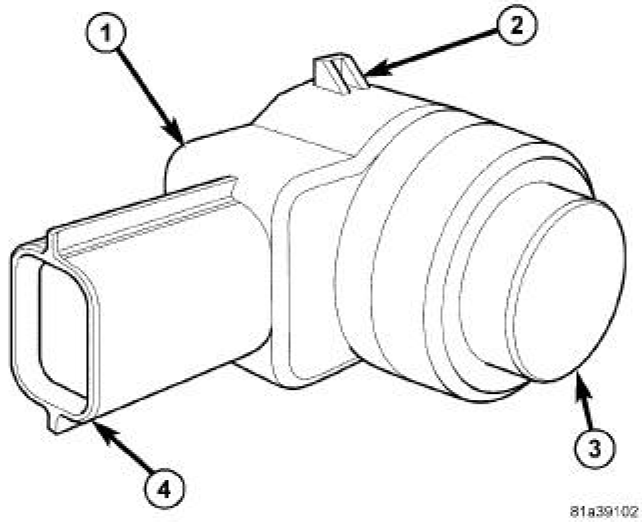

Fig. 9: Park Assist Sensor
Courtesy of CHRYSLER GROUP, LLC

Vehicles equipped with the rear park assist system have four park assist sensors (1) installed on the rear bumper fascia. Only the membrane (3) of each sensor is visible through a hole in the outer vertical surface of the fascia. The remainder of each sensor including the sensor mounting bracket, the sensor spacer and the sensor wiring connection is concealed behind the fascia. A sensor wire harness behind the fascia connects the sensors to the vehicle electrical system.

Each of the four sensors is identical in construction and is interchangeable. The electronic circuitry and a communication chip for each sensor is enclosed and protected within the molded black plastic sensor housing. The housing includes an integral connector receptacle (4) and two integral latch tabs (2). The sensor membrane extends from the surface of the sensor housing, and is finished to match the outer surface of the fascia.

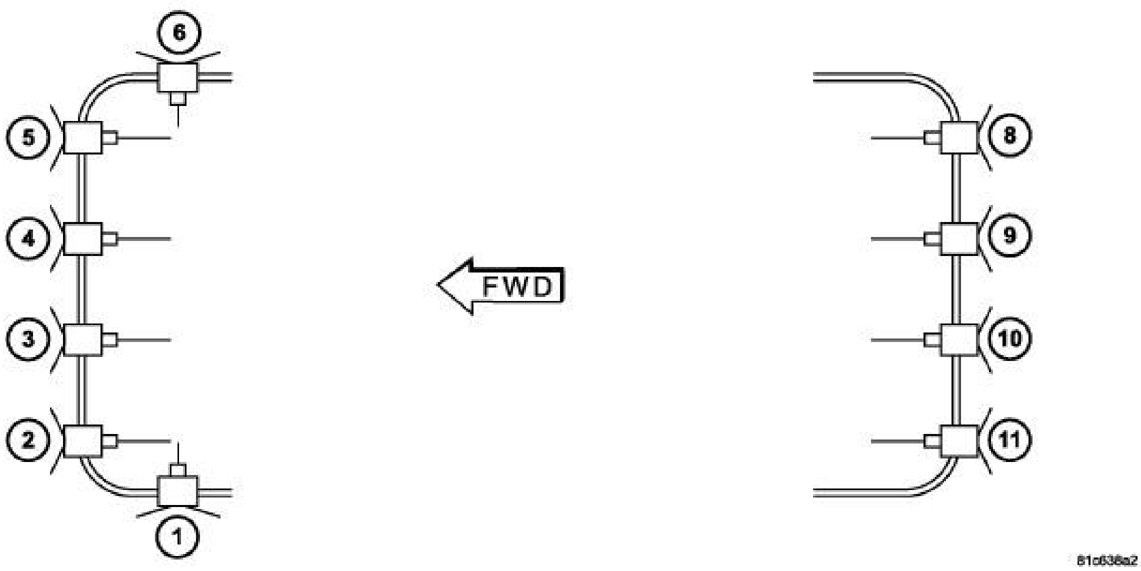

Fig. 10: Park Assist Sensors
Courtesy of CHRYSLER GROUP, LLC

The numbering system for the park assist sensors allows for up to twelve sensors on the vehicle, six front and six rear. The sensors are numbered in a clockwise manner starting at the left front bumper. The left front sensor (if the vehicle were equipped with front park assist) is the number 1 sensor. The numbering continues in a clockwise direction around the vehicle. Since this vehicle uses only four rear sensors, sensor numbers 7 and 12 are omitted, so the left rear sensor is the number 11 sensor.

A resilient O-ring spacer (also known as a decoupling ring) around the circumference of the membrane isolates the membrane from the openings in the fascia. Each sensor is snapped into its own dedicated molded plastic mounting bracket. Each sensor mounting bracket is heat-staked to the back side of the rear bumper fascia.

The park assist sensors cannot be adjusted or repaired. If a sensor is ineffective or damaged it must be replaced with a new unit. The sensor spacers are available for individual service replacement. The sensor mounting brackets are serviced only as a unit with the rear bumper fascia.

OPERATION

OPERATION

The park assist sensors are ultrasonic transceivers that are completely controlled by the Park Assist Module (PAM) (also known as the ParkTronic System/PTS module). The sensors transmit and receive ultrasonic signals. The sensors each receive battery current and ground in parallel from the PAM, but are each connected to individual dedicated serial bus communication circuits to the module.

Each sensor membrane is oscillated, then quieted by the PAM in a pulsing fashion. While the sensor membrane oscillates, it emits an ultrasonic signal. This signal will bounce or echo off of objects in the path of the vehicle. While quieted, each membrane receives the echoes of the ultrasonic signals it and the other sensors have transmitted. The sensors then communicate this echo data over the serial bus lines back to the PAM. The microcontroller within the PAM uses the intervals between the ultrasonic transmission and reception data from the sensors to calculate the distance to any obstacles identified by the ultrasonic echoes.

The hard wired circuits between components related to the park assist sensors may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the park assist sensors or the electronic controls and communication between modules and other devices that provide some features of the park assist system. The most reliable, efficient and accurate means to diagnose the park assist sensors or the electronic controls and communication related to park assist sensor operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - PARK ASSIST SENSOR

The hard wired circuits between the park assist sensors and the Park Assist Module (PAM) (also known as the ParkTronic System/PTS module) may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out

information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the park assist sensors or the electronic controls and communication between other modules and devices that provide some features of the park assist system. The most reliable, efficient and accurate means to diagnose the park assist sensors or the electronic controls and communication related to park assist sensor operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

REMOVAL

REMOVAL

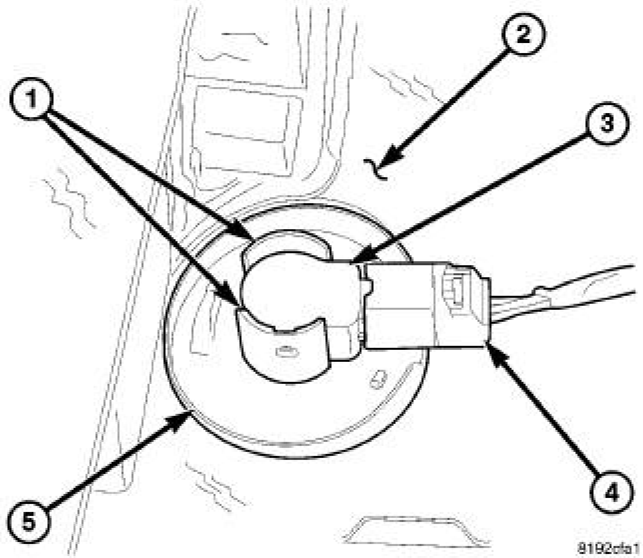
Courtesy of CHRYSLER GROUP, LLC

NOTE:	**The park assist sensors (3) and the sensor spacers (O-rings) are each available for separate service replacement. The sensor brackets (5) are bonded to and integral to the back side of the rear bumper fascia (2).**

1. Disconnect and isolate the negative cable from the battery. If equipped with an Intelligent Battery Sensor (IBS), disconnect the IBS connector before disconnecting the negative cable from the battery.
2. Remove the bumper fascia from the rear of the vehicle. Refer to FASCIA, REAR, REMOVAL and FASCIA, REAR, LOWER, REMOVAL .
3. From the back of the fascia (2), disconnect the wire harness connector (4) from the park assist sensor (3) connector receptacle.
4. Carefully pry the sensor bracket (5) latch features (1) away from the top and bottom latch tabs of the sensor far enough to disengage the sensor from the bracket.
5. Disengage the sensor spacer (O-ring) from around the circumference of the sensor membrane protrusion.

INSTALLATION

INSTALLATION



[Fig. 12: Identifying Latch Features, Rear Bumper Fascia, Park Assist Sensors, Park Assist Sensor]
Courtesy of CHRYSLER GROUP, LLC

NOTE: **The park assist sensors (3) and the sensor spacers (O-rings) are each available for separate service replacement. The sensor brackets (5) are bonded to and integral to the back side of the rear bumper fascia (2).**

NOTE: **Production and all service replacement O-ring spacers are tapered. The wide side (base) of the O-ring should be seated against the sensor housing and the narrow side should be oriented toward the outer surface of the sensor membrane and the rear fascia.**

1. If the park assist sensor or the sensor spacer are being replaced, engage the O-ring spacer around the circumference of the sensor membrane protrusion.
2. Align and insert the sensor into the sensor bracket on the back of the rear bumper fascia (2) until the bracket latch features (1) are fully engaged over the top and bottom latch tabs of the sensor.

   NOTE: **Be certain that each sensor membrane is properly centered in the openings of the rear fascia and that the O-ring spacers are not pinched. Improper centering or pinched O-rings can be detrimental to proper park assist sensor operation. Be certain that the sensor membrane is flush with the outer surface of the fascia.**

3. From the back of the fascia, reconnect the wire harness connector (4) to the sensor connector receptacle.
4. Reinstall the bumper fascia onto the rear of the vehicle. Refer to **FASCIA, REAR, INSTALLATION** and **FASCIA, REAR, LOWER, INSTALLATION** .
5. Reconnect the negative cable to the battery. If equipped with an Intelligent Battery Sensor (IBS), reconnect the IBS connector.

SWITCH, PARK ASSIST

DESCRIPTION

DESCRIPTION

Fig. 13: Integrated Center Stack (ICS), Park Assist Off & Heater/Air Conditioner Switch
Courtesy of CHRYSLER GROUP, LLC

The park assist Off switch (2) is integral to the instrument panel Integrated Center Stack (ICS) controls (also known as the lower switch bank), which is located behind the instrument panel center bezel just above the heater and air conditioner controls (3). Refer to **POD, SWITCH BANK, DESCRIPTION** .

The park assist Off switch push button is clearly identified with a white International Control and Display Symbol graphic for **Parking Aid** and the text **OFF** . An amber Light Emitting Diode (LED) unit is illuminated behind a small clear plastic jewel-like lens in the push button to give a visual indication whenever the park assist system has been manually disabled or is unavailable due to a detected system fault while the status of the ignition switch is On. The switch button also has panel lamps dimmer controlled illumination for night visibility.

All of the circuitry and components of the park assist Off switch are contained within a molded black plastic ICS switch pod housing. The ICS switch pod and display unit is connected to the vehicle electrical system through dedicated take outs and connectors of the instrument panel wire harness.

The park assist Off switch cannot be adjusted or repaired and, if the switch is ineffective or damaged, the entire ICS display and switch pod unit must be replaced with a new unit.

OPERATION

OPERATION

The status of the park assist controls is continually monitored by the circuitry within the instrument panel switch pod (also known as the Accessory Switch Bank Module/ASBM). The switch pod receives battery voltage at all times on a fused battery feed circuit and has a path to ground at all times through the instrument panel wire harness. The inputs to and outputs from the switch pod consist of electronic message communication with the Body Control Module (BCM) (also known as the Common Body Controller/CBC) over the single wire Local Interface Network (LIN) data bus.

Each time the park assist Off switch push button is depressed the switch pod circuitry sends an electronic **park assist switch status** message input to the BCM over the LIN data bus. The BCM then relays an electronic **park assist switch request** message to the Park Assist Module (PAM) over the Controller Area Network (CAN) data bus. The PAM responds to each **park assist switch request** message by toggling the status of the park assist system from enabled to disabled, or from disabled to enabled, then sends an electronic **park assist system status** message back to the BCM over the CAN data bus as confirmation.

The BCM responds to the system status message by sending a message to the switch pod over the LIN data bus to control the park assist Off switch Light Emitting Diode (LED) unit so that the LED is illuminated with the system disabled while the status of the ignition switch is On, and is extinguished with the system enabled or with the status of the ignition switch anything except On.

The hard wired circuits between components related to the park assist switch may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the electronic controls and communication between modules and other devices that provide some features of the park assist system. The most reliable, efficient and accurate means to diagnose the park assist switch or the electronic controls and communication related to park assist system operation requires the use of a diagnostic scan tool. Refer to the appropriate diagnostic information.

COMMUNICATION

DESCRIPTION

DESCRIPTION

This vehicle is equipped with the PowerNet electronic architecture.

The primary on-board communication network between microcontroller-based electronic control modules in this vehicle is the Controller Area Network (CAN) data bus system. A data bus network minimizes redundant wiring connections; and, at the same time, reduces wire harness complexity, sensor current loads and controller hardware by allowing each sensing device to be connected to only one module (also referred to as a node). Each node reads, then broadcasts its sensor data over the bus for use by all other nodes requiring that data. Each node ignores the messages on the bus that it cannot use.

The CAN bus is a two-wire multiplex system. Multiplexing is any system that enables the transmission of multiple messages over a single channel or circuit. The CAN bus is used for communication between most vehicle nodes. However, in addition to the CAN bus network, certain nodes may also be equipped with a Local Interface Network (LIN) data bus. The LIN data bus is a single wire low-speed (9.6 Kbps) serial link bus used to provide direct communication between a LIN master module and certain switch or sensor inputs.

There are actually two separate CAN bus systems used in the vehicle. They are designated: the CAN-IHS and the CAN-C. The CAN-IHS and CAN-C systems provide on-board communication between all of the nodes that are connected to them. The CAN-C is the faster of the two systems providing near real-time communication (500 Kbps). The CAN-C is used typically for communications between more critical nodes, while the slower (125 Kbps). The CAN-IHS system is used for communications between less critical nodes. This electronics architecture is called PowerNet.

The added speed of the CAN data bus is many times faster than previous data bus systems. This added speed facilitates the addition of more electronic control modules or nodes and the incorporation of many new electrical and electronic features in the vehicle.

The BCM is located under the instrument panel to right of the glove box. The central CAN gateway or hub module integral to the BCM is connected to CAN-IHS and CAN-C buses. This gateway physically and electrically isolates the CAN buses from each other and coordinates the bi-directional transfer of messages

between them.

OPERATION

OPERATION

The primary communication network between electronic control modules on this vehicle is the Controller Area Network (CAN) data bus system. The Controller Area Network (CAN) data bus allows all electronic modules connected to the bus to share information with each other. Regardless of whether a message originates from a module on the higher speed CAN C (500K) Bus or on the lower speed CAN Interior High Speed (IHS) (125K) Bus the message structure and layout is similar, which allows the Body Control Module (BCM) to be a Central GateWay to process and transfer messages between the CAN C and CAN IHS buses. The BCM also stores Diagnostic Trouble Codes (DTCs) for certain bus network faults. These data communication network is known as the **PowerNet** electronics architecture.

All modules transmit and receive messages over one of these buses. Data exchange between the modules is achieved by serial transmission of encoded data messages (a form of transmission in which data bits are sent sequentially, one at a time, over a single line). Each module can both send and receive serial data simultaneously. Each data bit of a CAN Bus message is carried over the bus as a voltage differential between the two bus circuits which, when strung together, form a message. Each module uses arbitration to sort the message priority if two competing messages are attempting to be broadcast at the same time. Corruption of a single bit within a message will corrupt the entire message. Each message contains a Cyclic Redundancy Check (CRC) which specifies the message size exactly. If the message detected conflicts with the CRC the ECU receiving it will determine the message to be an error and consider that communication has not been possible. Diagnosis of this condition using a lab scope may reveal activity that appears to be Bus data messages even if no actual communication is possible. Communication problems that affect the whole bus, as a result of opens and terminal push outs are more likely to occur on data busses that operate at a high speed than a data bus that operates at a lower speed.

When an open circuit or terminal push out occurs one or more modules can become isolated from the remainder of the bus. The isolated module will attempt to communicate, but will not be able to receive messages or determine arbitration from other modules. Each time the isolated module attempts to communicate it alters the bus voltage on the intact bus circuit. Without functioning arbitration the isolated module alters the bus voltage while other bus messages are being sent thereby corrupting the messages on the remainder of the bus.

The communication protocol being used for the CAN data bus is a non-proprietary, open standard adopted from the Bosch CAN Specification 2.0b. The CAN-C is the faster of the two primary buses in the CAN bus system, providing near real-time communication (500 Kbps). CAN-IHS communicate at (125 Kbps).

The CAN bus nodes are connected in parallel to the two-wire bus using a twisted pair, where the wires are wrapped around each other to provide shielding from unwanted electromagnetic induction, thus preventing interference with the relatively low voltage signals being carried through them. The twisted pairs have between 33 and 50 twists per meter (yard). While the CAN bus is operating (active), one of the bus wires will carry a higher voltage and is referred to as the CAN bus (+) wire, while the other bus wire will carry a lower voltage and is referred to as the CAN bus (-) wire. Refer to the CAN Bus Voltages chart .

Notes All measurements taken between node ground and CAN terminal with a standard DVOM. DVOM will display average network voltage. Total resistance of CAN networks can be measured with the battery disconnected. The average resistance is approximately 60 Ohms. The termination resistors are integral to the Star Connectors.

The CAN bus network remains active until all nodes on that network are ready for sleep. This is determined by the network using tokens in a manner similar to polling. When the last node that is active on the network is ready for sleep, and it has already received a token indicating that all other nodes on the bus are ready for sleep, it broadcasts a **bus sleep acknowledgment** message that causes the network to sleep. Once the CAN-IHS bus network is asleep, any node on the bus can awaken it by transmitting a message on the network. The BCM will keep either the CAN-IHS or the CAN-C bus awake for a timed interval after it receives a diagnostic message for that bus over the Diagnostic CAN-C bus.

In the CAN system, available options are configured into the BCM at the assembly plant, but additional options can be added in the field using the diagnostic scan tool. The configuration settings are stored in non-volatile memory. The BCM also has two 64-bit registers, which track each of the **as-built** and **currently responding** nodes on the CAN-IHS and CAN-C buses. The BCM stores a Diagnostic Trouble Code (DTC) in one of two caches for any detected active or stored faults in the order in which they occur. One cache stores powertrain (P-Code), chassis (C-Code) and body (B-Code) DTCs, while the second cache is dedicated to storing network (U-Code) DTCs.

CONNECTOR, STAR DIAGNOSTIC

DESCRIPTION

DESCRIPTION

Star connectors provide a simple method of diagnosing CAN Bus communication faults through the use of connection points for all modules on the bus. The connectors can be used to eliminate a module or group of modules in order to diagnose issues with the CAN Bus circuits and connectors to the modules or the modules themselves.

There are two locations for the STAR diagnostic connectors on this vehicle:

- The location of IP side CAN IHS Connectors - Behind the glove box on the passenger side. These connectors slide right to left in order to remove from the mounting bracket.
- The location of Body side CAN C Connectors - Drivers rear cargo area of the trunk compartment.

MODULE, ACTIVE DAMPING CONTROL

DESCRIPTION

DESCRIPTION

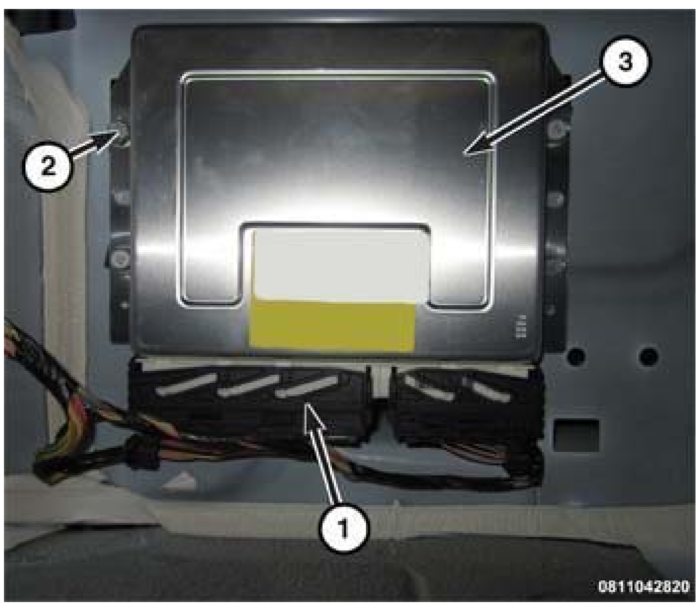

Fig. 1: Active Damping Control Module, Screws & Connectors
Courtesy of CHRYSLER GROUP, LLC

Vehicles equipped with Active Damping Suspension (ADS) have an Active Damping Control Module (ADCM). The ADCM (3) is located in the left side of the trunk and is retained by four mounting screws (2). The carpet on the left side of the trunk has to be repositioned to access the ADCM.

OPERATION

OPERATION

The Active Damping Control Module (ADCM) uses the CAN bus to communicate with multiple modules. The

ADCM has the following inputs: Vehicle Speed, Steering Angle Sensor (SAS) position, Throttle Position Sensor (TPS), Active Damping System (ADS) input switch, and 3 acceleration sensors. There are solenoid-controlled ADS valving units on each shock absorber assembly which are the outputs for the ADCM.

The ADS input switch is a soft touch button on the radio display. When the ADS input switch is pressed with the key in the ON or RUN position, a signal is sent over the CAN bus to the ADCM and the Transmission Control Module (TCM) to change modes. The resulting change is indicated on the radio display.

The Active Damping Control Module (ADCM) controls the suspension and ride for the SRT version of this vehicle by adjusting the rebound and jounce of the shock assemblies using the above information and predetermined settings for maximum vehicle control. The shock absorbers are unique to the Active Damping System (ADS). Each shock absorber has a valving unit that is external, but still part of the shock absorber. Inside each valving unit are two solenoids that control the damping valves to alter the ride of the vehicle. The shocks are replaced as an assembly, they cannot be disassembled for repair.

The two front acceleration sensors are mounted with one on each wheel well. The rear acceleration sensor is mounted in the right rear wheel well on the shock tower. The ADCM is located in the left side of the trunk.

REMOVAL

REMOVAL

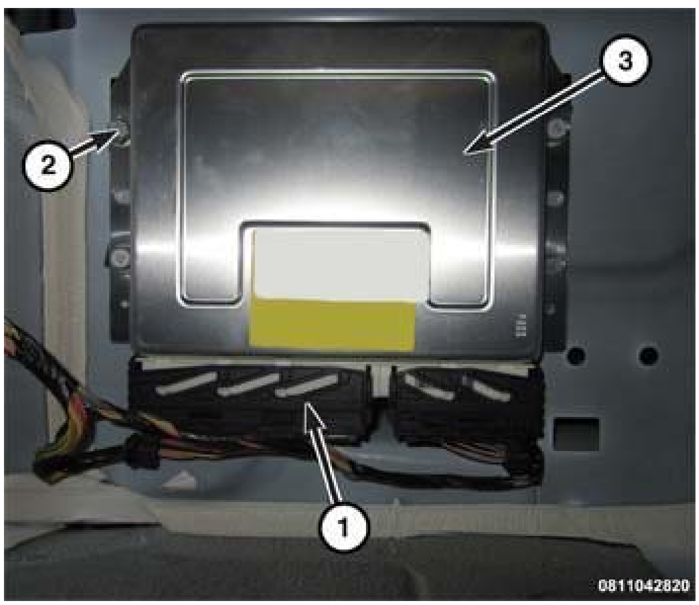

Fig. 2: Active Damping Control Module, Screws & Connectors
Courtesy of CHRYSLER GROUP, LLC

1. Disconnect and isolate the negative battery cable.
2. Remove the left rear wheel well carpet. Refer to **CARPET, REMOVAL** .
3. Disconnect the two wire harness connectors (1) and remove the four screws (2) from the Adaptive Damping Control Module (ADCM) (3).
4. Remove the ADCM from the vehicle.

INSTALLATION

INSTALLATION

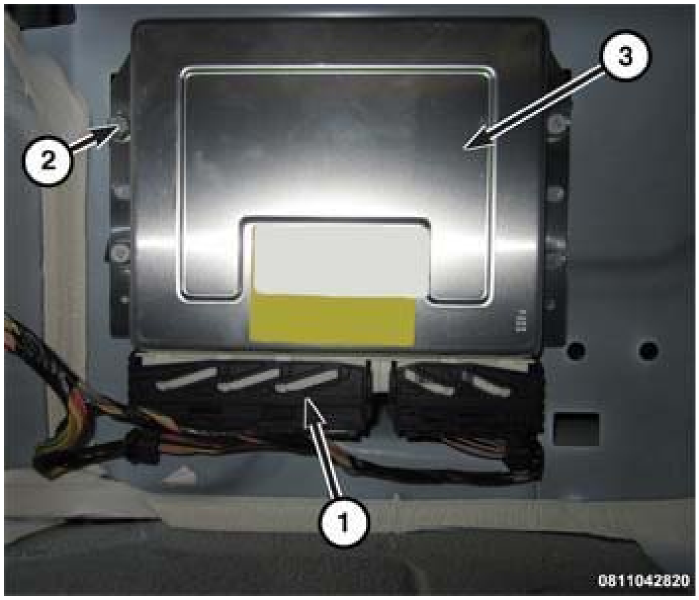

Fig. 3: Active Damping Control Module, Screws & Connectors
Courtesy of CHRYSLER GROUP, LLC

1. Place the Active Damping Control Module (ADCM) (3) into position and install the four ADCM retaining screws (2). Tighten to the proper **SPECIFICATIONS**.
2. Install the retaining screws (2) and tighten to 9 N.m (80 in. lbs.).
3. Connect the wire harness connectors (1) to the ADCM (3). Install the inner left rear wheel well carpet. Refer to **CARPET, INSTALLATION** .
4. Connect the negative battery cable.
5. Perform the ADCM Verification Test. Refer to **STANDARD PROCEDURE** .

MODULE, ADAPTIVE CRUISE CONTROL

DESCRIPTION

DESCRIPTION

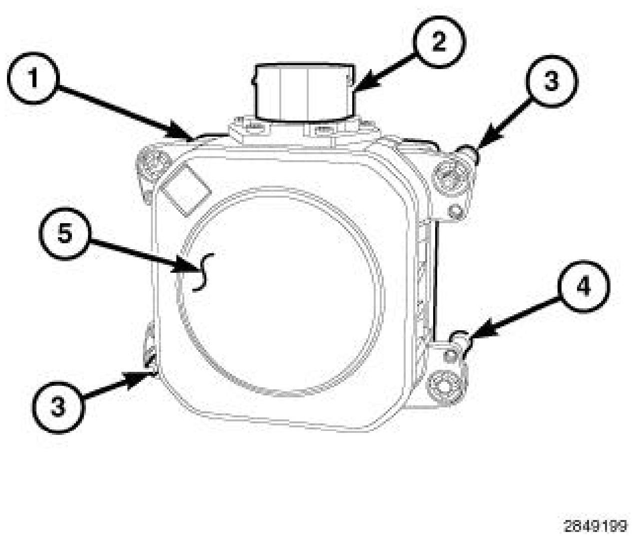

Fig. 4: Adaptive Speed Control Sensor, One Fixed Ball Stud, Two Adjustable Ball Studs & Radar Dome

The Adaptive Cruise Control (ACC) module (1) is mounted to the front bumper beam at the centerline of the vehicle. The stamped steel ACC module mounting bracket is secured by two screws to rivet nuts installed in the face of the bumper support member. This module is also the primary component of the Forward Collision Warning (FCW) feature of the Electronic Vehicle Information Center (EVIC).

One fixed ball stud (4) and two adjustable ball studs (3) secure the module housing through a pressed fit into molded plastic ball socket clips installed in the mounting bracket. The module pivots on the fixed ball stud while the two adjustable ball studs allow the module to be vertically aligned after installation.

The ACC module electronic circuitry is sealed and protected within a die cast aluminum housing. A molded plastic cover and a lens or radar dome (5) faces forward through an opening in the center of the front fascia lower airflow grille texture that is trimmed with a bezel snapped into the texture opening. A molded plastic module bezel or mirror cover with a center clearance hole for the module lens snaps over the module and conceals a small square mirror in one corner of the module cover that is used for calibration purposes during the module manufacturing process.

The ACC module includes an applied connector receptacle (2) that is sealed and secured to the module housing with screws and faces downward when installed on the mounting bracket. The ACC module is connected to the vehicle electrical system through a single dedicated takeout and connector of the FEM wire harness.

The adjustable ball studs and the ACC module cannot be repaired. If ineffective or damaged the entire module unit must be replaced. The ACC bracket assembly must be replaced if service is needed. This is to ensure proper functionality and the press fit nature of the clips.

OPERATION

OPERATION

The microcontroller within the Adaptive Cruise Control (ACC) module contains the logic circuits and controls many of the features of the adaptive speed control system. The ACC module receives battery voltage on a fused ignition switch output (run) circuit and is grounded at all times through a hard wired remote ground point. These connections allow the ACC module to operate only when the ignition switch is in the ON position. Likewise, the ACC module sleeps whenever the ignition switch is in any position except RUN.

The ACC module is also a Radio Detection And Ranging (RADAR) transceiver. The ACC module transmits electromagnetic signal bursts at an operating frequency of 77 gigahertz. Those signal bursts are scattered by any objects they strike within the 40 degree field of view of the transceiver, which changes the strength and frequency of the signal. The ACC module antenna receives and interprets the returned signals to detect any objects in the path of the vehicle as well as their speed and direction.

The ACC module receives electronic speed control switch status message inputs from the microcontroller integral to the Steering Column Control Module (SCCM) over the Controller Area Network (CAN) data bus. The module also monitors electronic message inputs from the Powertrain Control Module (PCM), the Antilock Brake System (ABS) Module and the Transmission Control Module (TCM).

The ACC module logic processes all of those inputs, then provides the appropriate electronic message outputs over the CAN data bus to the PCM, the TCM and the ABS to control and maintain the separation setting selected by the vehicle operator between the vehicle and any preceding vehicles. The ACC module also provides electronic message outputs to the Instrument Panel Cluster (IPC) and the Electronic Vehicle Information Center

(EVIC) to invoke the Forward Collision Warning (FCW) features.

The module also contains an electronic ambient temperature module and a heating element. When appropriate ambient temperatures are sensed, the heating element is energized by the ACC module control circuitry to keep the module lens or radar dome clear of ice and snow accumulations that might otherwise blind the module to proper reception of returned signals.

The ACC module microcontroller continuously monitors all of its internal electronics to determine the module readiness. If the ACC module detects a monitored module fault, it sets and stores a Diagnostic Trouble Code (DTC). The ACC module uses On-Board Diagnostics (OBD) and can communicate with other electronic modules in the vehicle as well as with the diagnostic scan tool over the CAN data bus. This method of communication is used for control of the indicators and indications provided to the vehicle operator through the Instrument Panel Cluster (IPC) and the EVIC. The ACC module is also Flash programmable, allowing the module software to be updated using a diagnostic scan tool.

The hard wired inputs for the ACC module may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the ACC module or the electronic controls or communication between other modules and devices that provide features of the ACC and FCW system features. The most reliable, efficient, and accurate means to diagnose the ACC module or the electronic controls and communication related to ACC or FCW system operation requires the use of a diagnostic scan tool. Refer to the appropriate Diagnostic & Testing article.

REMOVAL

SENSOR AND BRACKET

1. Disconnect and isolate the battery negative cable.
2. Raise and support the vehicle.
3. Remove the front fascia from the vehicle. Refer to **FASCIA, FRONT, REMOVAL** .

6. Remove the two screws (2) that secure the bracket (1) to the front bumper support bar.
7. Remove the mounting bracket from the bumper support bar.

INSTALLATION

SENSOR AND BRACKET

1. Check to be certain that the two rivet nuts are properly installed and in good condition in front bumper support bar.
2. Position the mounting bracket to the bumper support bar.

5. Connect the wiring harness connector (1) to the ACC sensor module.
6. Install the front fascia. Refer to **FASCIA, FRONT, INSTALLATION** .
7. Connect the negative battery cable.
8. Perform the ACC module alignment procedure. Refer to **MODULE, ADAPTIVE CRUISE CONTROL, MODULE PROGRAMMING**.

MODULE PROGRAMMING

ADAPTIVE SPEED CONTROL MODULE - ALIGNMENT

The Adaptive Cruise Control (ACC) module requires alignment when the:

- ACC module is removed and reinstalled
- Front end structural repairs are performed
- A Diagnostic Trouble Code (DTC) indicates ACC adjustment is required
- Any suspension or vehicle alignment changes

ACC module alignment consists of performing the mechanical vertical alignment described in the following procedure, followed by the electronic horizontal alignment that is performed with a diagnostic scan tool and the appropriate diagnostic information.

VEHICLE PREPARATION FOR MODULE ALIGNMENT

NOTE: **The ACC module lens could be obstructed by snow/ice, dirt, mud, and other environmental debris. A message will appear on dash to clean the lens when needed. The module lens is equipped with a heating element that can melt snow/ice. Otherwise the lens must be cleaned manually. Also note that the assembly could be misaligned or damaged from impact or water intrusion.**

1. Repair or replace any ineffective, worn or damaged body components. Repair any loose or cracked fascia components that might interfere with the sensor field of view. The lens dome of the module should be roughly centered in the opening of the fascia.
2. Verify proper tire inflation pressures.
3. Remove any accumulations of mud, snow or ice from the vehicle underbody.
4. Verify that there is no load in the vehicle (cargo or passengers), except for the driver.

   NOTE: **The vehicle MUST be placed upon a wheel alignment or frame rack to achieve the proper module vertical alignment results. If a wheel alignment or frame rack is not available, then a verified level surface can be used. When using the wheel alignment rack, the fore - after specifications must be within 0 (+/- 0.2) degrees.**

5. Rock the vehicle side-to-side three times to allow the suspension to stabilize.
6. Bounce the front and rear suspension three times by pushing downward on the front and rear bumpers and releasing.
7. Verify correct vehicle suspension height.

MODULE ALIGNMENT

1. The Adaptive Cruise Control (ACC) module is located on a bracket secured near the center of the underside of the front bumper support member of the Front End Module (FEM) behind the front fascia.

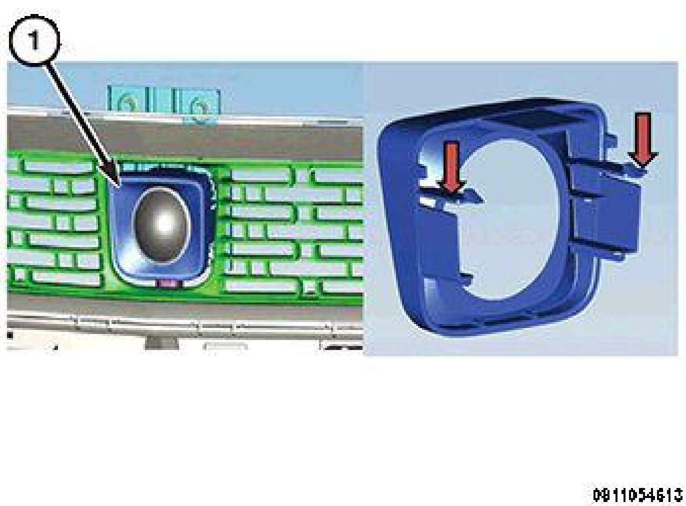

Fig. 9: Adaptive Cruise Control Mirror Cover
Courtesy of CHRYSLER GROUP, LLC

2. Remove the ACC mirror cover (1). Remove the mirror cover by pushing down on the two attachment levers shown in the supplied graphic and then pulling outward on the cover. This is done without removal of the fascia.
3. Using standard glass cleaner and a clean soft towel, remove any dirt or road salt from the convex molded dark plastic lens dome on the face of the ACC module as well as from the suction cup of the vertical alignment tool.
4. Carefully slide the vertical alignment tool over the sensor housing until the suction cup rests against the lens of the ACC module.

NOTE: **It may take several attempts to get the suction cup of the special tool to fasten securely to the ACC module. If necessary, lightly wet the suction cup with clean water to help improve adhesion.**

5. Depress the plunger of the vertical alignment tool to engage the suction cup and attach the special tool securely to the lens of the ACC module.

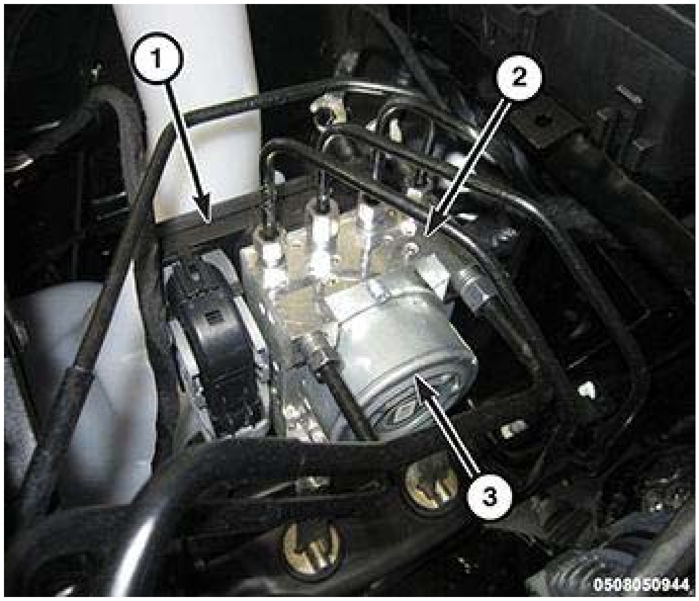
6. Use the 3.5 millimeter hex nut driver (Special Tool No. (special tool #10243-2, Driver, Nut)) to rotate the vertical adjustment ball stud (2) that secures the sensor (1) to the mounting bracket as necessary to center the bubble of the spirit level between the two center marks on the vial of the level located on the top of the vertical alignment tool.
7. Depress the center release button of the special tool to release the suction cup from the sensor lens and remove the special tool from the ACC module.
8. Perform service drive alignment.
9. Perform the "ACC aim mode auto alignment". This is the ACC sensors horizontal alignment procedure. Perform this routine using a diagnostic scan tool and follow the directions on the screen. The use of the 3.5 mm hex nut driver (Special Tool No. 10243-2) may be needed for the procedure.
10. Install the mirror cover onto the front of the module. Press down around the outside edges of the mirror

cover to ensure the cover is fully engaged to the module housing

MODULE, ANTI-LOCK BRAKE SYSTEM

DESCRIPTION

DESCRIPTION



[Fig. 11: Antilock Brake Module (ABM) & Hydraulic Control Unit (HCU)]
Courtesy of CHRYSLER GROUP, LLC

NOTE:	**The Electronic Stability Control (ESC) may also be referred to as Electronic Stability Program (ESP) depending on the vehicle model year and configuration. Certain components may also reference ESP, ESC, or use the traction control symbol.**

The Anti-lock Brake System (ABS) Module is a microcontroller-based device which monitors the anti-lock brake system during normal braking and controls it when the vehicle is in an ABS stop. The ABS module also monitors the Electronic Stability Control (ESC).

The ABS module (1) is mounted to the HCU (2) as part of the Integrated Control Unit (ICU). The ABS module uses a 38-Way connector on the vehicle wiring harness. The power source for the ABS module is through the ignition switch in the RUN or ON position. The ABS module is on the CAN-C bus.

OPERATION

OPERATION

The primary functions of the Anti-lock Brake System (ABS) module are to:

- Monitor the Anti-lock Brake System (ABS) module and Electronic Stability Program (ESP) for proper operation.
- Detect wheel locking or wheel slipping tendencies by monitoring the speed of all four wheels of the vehicle.

- Control fluid modulation to the wheel brakes while the system is in ABS or traction control mode.
- Modulates fluid pressure to the wheel brakes to control vehicle yaw rate in ESP mode.
- Store diagnostic information.
- Provide communication to the scan tool while in diagnostic mode.
- Illuminate the amber TCS/ESP indicator in the instrument cluster.

The ABS module constantly monitors the ABS and ESP (if equipped) for proper operation. If the ABS module detects a fault, it will turn on the amber TCS/ESP indicator and disable the ABS or ESP if so equipped. The normal base braking system will remain operational at that time.

The ABS module continuously monitors the speed of each wheel through the signals generated by the wheel speed sensors to determine if any wheel is beginning to lock. When a wheel locking tendency is detected, the ABS module commands the solenoid coils to actuate. The coils then open and close the valves in the HCU that modulate brake fluid pressure in some or all of the hydraulic circuits. The ABS module continues to control pressure in individual hydraulic circuits until a locking tendency is no longer present.

REMOVAL

REMOVAL

1. To replace the ABM, the ICU assembly must be removed. Refer to **INTEGRATED CONTROL UNIT (ICU), REMOVAL** .
2. Remove two screws attaching the mounting bracket to the HCU. Remove the bracket.

4. Separate ABM (1) from HCU (2).

INSTALLATION

INSTALLATION

1. Clean any debris off the mating surfaces of the HCU and ABM.

NOTE: When installing a new ABM seal, do not use any type of lubricant.

MODULE, BODY CONTROL

DESCRIPTION

DESCRIPTION

A Body Control Module (BCM) is an electronic control unit with a microcontroller that controls and integrates many of the main body electronic functions and features of the vehicle. Many of the functions and features provided by the BCM are possible because of numerous hard wired inputs and outputs, but most of these features are only possible or are enhanced because the BCM communicates electronically with other electronic modules in the vehicle as well as with a diagnostic scan tool using the Controller Area Network (CAN) data bus.

The BCM is located behind the passenger side door kick panel. The BCM has a molded plastic case that is secured with screws within two stamped metal brackets that form a mounting yoke. The yoke is then secured with screws to a metal support structure. The BCM is connected to the vehicle electrical system through wire harness connections.

The BCM is a gateway between the high and low speed CAN data bus networks as well as a Local Interface Network (LIN) master node. This method of communication allows the sharing of sensor information, which reduces wire harness complexity, internal controller hardware and component sensor current loads. At the same time, this system provides increased reliability, enhanced diagnostics and allows the addition of many new feature capabilities. This method of communication is used by the BCM to acquire vehicle configuration data, including customer programmable features.

OPERATION

OPERATION

A Body Control Module (BCM) is an electronic control unit with a microcontroller that controls and integrates many of the main body electronic functions and features of the vehicle. Many of the functions and features provided by the BCM are possible because of numerous hard wired inputs and outputs, but most of these features are only possible or are enhanced because the BCM communicates electronically with other electronic modules in the vehicle as well as with a diagnostic scan tool using the Controller Area Network (CAN) data bus.

The BCM is a gateway between the high and low speed CAN data bus networks as well as a Local Interface Network (LIN) master node. This method of communication allows the sharing of sensor information, which reduces wire harness complexity, internal controller hardware and component sensor current loads. At the same time, this system provides increased reliability, enhanced diagnostics and allows the addition of many new feature capabilities. This method of communication is used by the BCM to acquire vehicle configuration data, including customer programmable features.

Software programming allows the BCM microcontroller to monitor all of these inputs and provide the appropriate outputs through high side drivers, low side drivers, on-board relays, Pulse-Width Modulation (PWM) and electronic messages to other modules in the vehicle. Some of the functions and features that the BCM supports or controls include:

- **Brake Fluid Level** - The BCM continuously monitors the brake fluid level sensor through a hard-wired input to monitor the brake fluid level. The BCM transmits an electronic message over the Can data bus to Instrument Cluster (IC) to illuminate the Low Fluid indicator based on the input signal received from the fluid level sensor.
- **Enhanced Accident Response Support** - The BCM monitors an input from the Occupant Restraint Controller (ORC) and, following an airbag deployment, will immediately disable the power lock output, unlock all doors by activating the power unlock output, then enables the power lock output if the power lock switch input remains inactive for two seconds. The BCM also monitors an input from the Powertrain Control Module (PCM) to automatically turn ON the interior lighting after an airbag deployment event, 10 seconds after the vehicle speed is zero. The interior lighting remains illuminated until the ignition switch is turned to the OFF position, at which time the interior lighting returns to normal operation and control. These Enhanced Accident Response System (EARS) features are each dependent upon a functional vehicle electrical system following the vehicle impact event.
- **Exterior Lighting Switch Support** - The BCM continuously monitors the headlamp switch position to activate or deactivate the exterior lighting. The headlamp switch provides the appropriate resistor multiplexed output hardwired to the BCM. The BCM reads and responds to this input by energizing or de-energizing the right and left park lamp feed circuits and the right and left high or low beam driver circuits through internal High Side Drivers (HSD) and by sending an electronic confirmation message back to the IC, which controls the high beam indicator as appropriate. The BCM also remembers which headlamp beams were last selected with the multi-function switch, and energizes those beams by default the next time the headlamps are turned ON. If the vehicle is equipped with optional automatic headlamps and the **A** (Automatic) position is selected, the BCM also monitors an electronic **ambient light level** message received over the CAN data bus from the Heat, Ventilation and Air Conditioning (HVAC) control module based upon a hard wired input from the rain sensor to turn the exterior lighting ON and OFF automatically while the ignition switch is in the ON position. The BCM also controls the fog lamps, CHMSL. front combination lamps, and rear combination lamps.
- **Fuel Level Data Support** - The BCM provides a current source for and receives a hard-wired analog input

from the fuel level sending unit located on the fuel pump module in the fuel tank. Based upon this input, the BCM uses electronic messaging to transmit this data over the CAN data bus for use by other electronic modules in the vehicle. The IC calculates the proper fuel gauge needle position and to control low fuel indicator operation based on these messages.

- **Hazard Lamp Circuit Control** - The BCM monitors an input from the hazard switch and receives a hard-wired analog input from the switch. The BCM reads and responds to this input by energizing or de-energizing the right and left turn lamp feed circuits through internal HSD units and by sending an electronic confirmation message to the IC over the CAN data bus, which controls the hazard light indicators as appropriate.
- **Ignition On and Ignition Accessory/On Relay Control** - The BCM monitors electronic **ignition switch status** messages received over the CAN bus from the RF hub and provides high side driver outputs to control both the ignition ON and ignition ACCESSORY/ON relays in the Power Distribution Center (PDC) as appropriate.
- **Interior Lamp Load Shedding** - The BCM provides a battery saver feature which will automatically turn OFF all interior lamps if they remain ON after a timed interval of about eight minutes.
- **Interior Lighting Control** - The BCM monitors electronic messages and hard-wired inputs from the interior lighting switch, the door ajar switches, the decklid ajar, the reading lamp switches and the RF hub to provide courtesy lamp control. This includes support for timed illuminated entry with theater-style fade-to-OFF and courtesy illumination DEFEAT features.
- **Local Interface Network Master Module** - The BCM is the master module for the LIN data bus. In this role it gathers information from the compass sensor, the Intelligent Battery Sensor (IBS), Humidity Sensor, Rear View Camera, the EVIC switches (Steering Column switches) and the Rain Sensor (RLS), then either acts on that information directly or places electronic messages on the CAN data bus for use by other modules.
- **Power Lock System Control** - The BCM monitors inputs from the power lock switches and the RF hub to provide control of the power lock motors through high side and low side driver outputs. This includes support for rolling door locks (also known as automatic door locks), automatic door unlock, and a door lock inhibit mode.
- **Remote Radio Switch Support** - The BCM receives electronic message inputs from the remote radio switches on the steering wheel over the LIN data bus, then provides electronic radio request messages over the CAN data bus to support the remote radio switch function.
- **Remote Start System Support** - The BCM receives electronic message inputs from the RF hub and then displays the appropriate remote start system textual reminder messages to the vehicle operator within the EVIC display.
- **Shipping Mode** - The new Chrysler Telematics Platform (CTP) vehicles no longer have a IOD fuse to use when transporting or storing for a long period of time. The BCM has a mode that takes the place of pulling the IOD fuse called **"Shipping Mode"** that is easily enabled or disabled.
- **Vehicle Theft Security System Control** - The BCM monitors inputs from the door ajar switches, and the RF hub, on vehicles so equipped. The intrusion module provides electronic **horn** and **lighting request** messages to the BCM for the appropriate VTSS alarm output features.
- **Washer Fluid Level** - The continuously monitors the washer fluid level sensor through a hard-wired input to monitor washer fluid level. the BCM transmits an electronic message over the Can data bus to Instrument Cluster (IC) to illuminate the Low Washer Fluid indicator based on the input signal received from the fluid level sensor.

The BCM uses On-Board Diagnostics (OBD) to monitor all of the systems and circuits it controls, then sets active and stored Diagnostic Trouble Codes (DTC) for any monitored system faults it detects. The BCM will also send electronic message requests to the Instrument Cluster (IC) (also known as the Instrument Panel Cluster/IPC) for the display of certain textual warning messages related to some detected system conditions or faults.

The hard wired inputs and outputs of the BCM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the BCM electronic controls or the communication between modules and other devices that provide some features of the BCM-controlled systems. The most

reliable, efficient and accurate means to diagnose the BCM or the electronic controls and communication related to BCM-controlled systems operation requires the use of a diagnostic scan tool. Refer to the appropriate Diagnostic & Testing article.

BATTERY SAVER MODE/BATTERY SAVER ON MESSAGE - IF EQUIPPED

Electrical Load Reduction Actions

This vehicle is equipped with an Intelligent Battery Sensor (IBS) to perform additional monitoring of the electrical system and status of the vehicle battery.

In cases when the IBS detects charging system failure, or the vehicle battery conditions are deteriorating, an electrical load reduction actions will take place to extend the driving time and distance of the vehicle. This is done by reducing power to or turning off non-essential electrical loads.

Load reduction is only active when the engine is running. It will display a message if there is a risk of battery depletion to the point where the vehicle may stall due to lack of electrical supply, or will not restart after the current drive cycle.

When load reduction is activated, the message "Battery Saver On" or "Battery Saver Mode" will appear in the Electronic Vehicle Information Center (EVIC) or Driver Information Display (DID).

These messages indicate the vehicle battery has a low state of charge and continues to lose electrical charge at a rate that the charging system cannot sustain.

NOTE:

- The charging system is independent from load reduction. The charging system performs a diagnostic on the charging system continuously.
- If the Charging System Light is on it may indicate a problem with the charging system.

The electrical loads that may be switched off (if equipped), and vehicle functions which can be effected by load reduction:

- Heated Seat/Vented Seats/Heated Wheel
- Heated/Cooled Cup Holders
- Rear Defroster And Heated Mirrors
- HVAC System
- 115V AC Power Inverter System
- Audio and Telematics System

Loss of the battery charge may indicate one or more of the following:

- The charging system cannot deliver enough electrical power to the vehicle system because the electrical loads are larger than the capability of charging system. The charging system is still functioning properly.
- Turning on all possible vehicle electrical loads (e.g. HVAC to max settings, exterior and interior lights, overloaded power outlets +12V, 115V AC, USB ports) during certain driving conditions (city driving, towing, frequent stopping).
- Installing options like additional lights, up-fitters, audio systems, alarms and similar devices.

- Unusual driving cycles (short trips separated by long parking periods).
- The battery aging.
- The vehicle was parking for extended period of time (weeks, months).
- The battery was recently replaced and was not charged completely.
- The battery was discharged by an electrical load left on when the vehicle is parked.
- The battery was used during parking time to supply radio, lights, chargers, +12V portable appliances like vacuum cleaner's, game consoles and similar devices.

What to do when the electrical load reduction actions message is present ("Battery Saver On" or "Battery Saver Mode")

- During trip, reduce power to unnecessary loads if possible:

- Turn off redundant lights (interior or exterior)
- Check what may be plugged in to power outlets +12V, 115V AC, USB ports
- Check HVAC settings (blower, temperature)
- Check the audio settings (volume)

After trip:

- Check if any aftermarket equipment was installed (additional lights, up-fitters, audio systems, alarms) and review specifications if any (load and Ignition Off Draw currents).
- Evaluate the latest driving cycles (distance, driving time and parking time).
- Review the chapter of this owner's manual regarding the battery maintenance.

REMOVAL

REMOVAL

WARNING: To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.

1. Disconnect and isolate the negative battery cable.
2. Remove the glove box assembly (1). Refer to GLOVE BOX, INSTRUMENT PANEL, REMOVAL .

3. Disconnect all of the electrical connectors from the Body Control Module (BCM) receptacles.
4. Remove the fastener (3) at the bottom of the BCM.
5. Loosen the top fasteners (1). These fasteners only have to be loosened to allow removal of the BCM. They do not need to be completely removed in order to remove the module.
6. Pull the module away from the side bulk head and down and remove the module.
7. Remove the BCM from the vehicle.

INSTALLATION

INSTALLATION

1. Slide the BCM into position so that the top two mounting tabs (1) on the BCM are properly aligned to the mounting weld studs and the lower mounting tabs slide into their respective mounting weld studs.
2. Install the lower fastener (3), and tighten the securely.
3. Tighten the upper fasteners securely.
4. Connect the electrical connectors to the BCM receptacles.
5. Install the glove box assembly (1). Refer to **GLOVE BOX, INSTRUMENT PANEL, INSTALLATION** .
6. Connect the negative battery cable.

NOTE: **Program the BCM in accordance with the module replacement and programming guide. Refer to STANDARD PROCEDURE.**

MODULE, COMBINED REAR VIEW MIRROR

DESCRIPTION

DESCRIPTION

The Combined Rear View Multiple Mirror Module (CRVV) is an available factory installed component on this vehicle. The CRVV combines the following modules and items:

- Electro-Mechanical Mirror Module (EMCC).
- Compass Module. **Note:** If the radio module supports navigation, standalone compass module will not be present on the vehicle.
- Auto High Beam Features.
- Two hard wired telematic microphones integral to the housing.

The CRVMM is secured to the same mounting button on the inside of the windshield glass and in the same manner that is used to mount the standard equipment mirrors.

OPERATION

OPERATION

Electrochromic Inside Rear View Mirror - Refer to **MIRROR, AUTOMATIC DAY AND NIGHT, DESCRIPTION** for description and operation characteristics of the mirror assembly.

Remote Compass Module (RCM) - If the vehicle is not equipped with navigation, the RCM will be located within the Combined Rear View mirror Module (CRVMM). The RCM is only serviced by replacing the CRVMM.

Auto High Beam Module (SmartbeamÂ® Module) - The module is integral to the CRVMM. Refer to **OPERATION** for description and operation of the SmartbeamÂ® lighting system.

REMOVAL

REMOVAL

Refer to **MIRROR, REARVIEW, REMOVAL** for removal of the Combined Rearview Mirror Module (CRVMM).

MODULE, DOOR

DESCRIPTION

DESCRIPTION

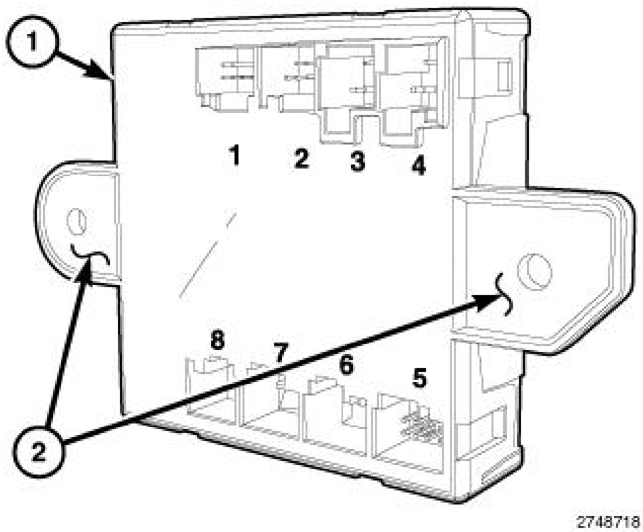

Fig. 19: Identifying Front Door Control Module
Courtesy of CHRYSLER GROUP, LLC

This vehicle is equipped with two electronic front door control modules (1) (Driver Door Module/DDM and a Passenger Door Module/PDM), one each on both the driver and passenger front doors. Each door control module is concealed behind the front door trim panel where it is secured through two integral mounting tabs (2) to the door hardware module carrier by two screws. The front door control modules are located in the upper front corner of the front door hardware carriers, just below the mirror flag area of the front door.

Each door control module contains a microcontroller and is connected to the various switches on that door. In the case of the driver side module, it communicates with some switches over a Local Interface Network (LIN) data bus. Both the driver and passenger side module also receive various hard wired switch inputs and provide numerous hard wired outputs to various devices located on their respective doors. In addition, both front door control modules communicate with each other and with other electronic modules in the vehicle over the Controller Area Network (CAN) Interior High Speed (IHS) data bus system.

Concealed and protected within the molded plastic door control module housing is the printed circuit board and the other electronic circuitry of the module. The front door control modules are connected to the vehicle electrical system through up to eight connector receptacles that are integral to the module housing.

A door control module cannot be adjusted or repaired and, if damaged or ineffective, it must be replaced. The door control module software is flash programmable.

OPERATION

OPERATION

The microcontroller-based electronic front door control modules (also known as a Driver Door Module/DDM and a Passenger Door Module/PDM) contain logic circuits that monitor various hard wired low current, multiplexed inputs from the power window, power lock, power mirror and memory switches on their respective door. They also receive Controller Area Network (CAN) Interior High Speed (IHS) data bus electronic message-based external inputs from the opposing front door control module as well as from other electronic modules in the vehicle. The front door control modules also monitor hard wired power window motor Hall effect sensors and memory mirror position sensor inputs.

In addition, the front door control module on the driver side front door receives electronic message inputs from the driver side front door switch module over the Local Interface Network (LIN) data bus network. The program logic within the front door control module allows the microcontroller to prioritize all of these inputs and determine the tasks it needs to perform. These tasks are then completed either by controlling hard wired outputs to the various motors, actuators or lamps on its own, or by sending electronic message requests over the CAN-IHS bus to the appropriate electronic module in the vehicle.

The front door control modules are powered by a fused B(+) circuit and are grounded at all times so that they can operate regardless of the ignition switch position. Both driver and passenger door control modules provide active and stored Diagnostic Trouble Codes (DTC) through On-Board Diagnostics (OBD) and communicate with a diagnostic scan tool using the CAN data bus.

The hard wired inputs and outputs of the front door control module may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the electronic controls and communication between modules and other devices that provide some features of the power window, power lock, memory, interior lighting or exterior lighting system features the front door control modules provide. The most reliable, efficient and accurate means to diagnose the front door control modules or the electronic controls and communication related to operation of these systems requires the use of a diagnostic scan tool. Refer to the appropriate Diagnostic & Testing article.

REMOVAL

REMOVAL

Courtesy of CHRYSLER GROUP, LLC

1. Disconnect and isolate the battery negative cable.
2. Remove the trim panel from the inside of the front door. Refer to **PANEL, DOOR TRIM, REMOVAL** .
3. Disconnect each of the electrical connectors (3) from the connector receptacles of the door control module (2).
4. Remove the two screws (4) that secure the door control module to the front door hardware module carrier (1).
5. Remove the door control module from the door hardware module carrier.

INSTALLATION

INSTALLATION

1. Position the door control module (2) to the front door hardware module carrier (1).
2. Install and tighten the two screws (4) that secure the door control module to the front door hardware module carrier. Tighten the screws securely.
3. Reconnect each of the electrical connectors (3) to the connector receptacles of the door control module.
4. Reinstall the trim panel to the inside of the front door. Refer to **PANEL, DOOR TRIM, INSTALLATION** .
5. Reconnect the battery negative cable.
6. The manual relearn procedure should be performed following service of a door control module so that the module can learn the correct hard stops of the power window regulator. Refer to **STANDARD PROCEDURE** .

MODULE PROGRAMMING

DOOR MODULE LEARN PROCEDURES

NOTE:

- **This procedure must be performed anytime the power window system has been serviced in either front door or when there is a possible concern with a door module calibration.**
- **The battery must be fully charged or the vehicle running before proceeding with the learn procedure.**
- **All doors must be completely closed before proceeding.**
- **It is suggested to sit inside the vehicle in the drivers seat and close the door.**

Express-up / Express-down possible concerns.

- Glass will not lower all the way down flush to the belt-line.
- Glass will not raise fully; wind noise / water leak.
- Glass will not raise automatically (Expess-up) after lifting the switch to the second detent and releasing.

To relearn the door module memory after module replacement, perform the following procedure:

1. Check and repair any door module Diagnostic Trouble Code (DTC) (s) unrelated to missing calibration before proceeding.
2. Using the window switch, lower the door glass to the full-down position by pushing down (depress) the window switch to its second detent and hold the switch until the door glass is fully open. Continue to hold the window switch down for two seconds after the door glass is fully open.
3. Raise the door glass to the full-up position by pulling up on the window switch and hold the switch until the door glass is fully closed. Continue to hold the window switch up for two seconds after the door glass is full closed.
4. Code should now be stored. Clear code and test window operations.

To relearn the door module memory after window/regulator replacement, perform the following procedure:

1. Using the scan tool, go to the network topology screen.
2. Click on the Diagnostic Procedures tab at the lower portion of the screen.
3. Run ECU Reset for DDM/PDM.
4. DDM/PDM calibration missing DTC will now set.
5. Using the window switch, lower the door glass to the full-down position by pushing down (depress) the window switch to its second detent and hold the switch until the door glass is fully open. Continue to hold the window switch down for two seconds after the door glass is fully open.
6. Raise the door glass to the full-up position by pulling up on the window switch and hold the switch until the door glass is fully closed. Continue to hold the window switch up for two seconds after the door glass is full closed.
7. DTC will now be stored. Clear code and test window operations.

MODULE, ELECTRIC POWER STEERING

DESCRIPTION

DESCRIPTION

This vehicle features an Electric Power Steering (EPS) system. The EPS module is located in a powerpack that contains the motor, module and worm drive on the steering gear assembly. Since the steering system is fully electric - rather than traditional hydraulic - all of the power assist is provided via an electric motor system. This improves fuel economy, since there is no parasitic loss from a power steering pump, and reduces steering system-generated noise, and allows optimal tuning of feedback to the driver.

NOTE: **All diagnostics must be done through the electric power steering module for the electric power steering system. (Refer to STANDARD PROCEDURE). There are no serviceable parts inside the steering rack, module or EPS motor. If any part is found to be defective or needs replacement, motor, and module are serviced as a assembly.**

For the removal of the EPS module and installation, refer to **GEAR, REMOVAL** and **GEAR, INSTALLATION** .

OPERATION

OPERATION

NOTE: **All diagnostics must be done through the electric power steering module for the electric power steering system. (Refer to STANDARD PROCEDURE). There are no serviceable parts inside the column, module or motor. If any part is found to be defective or needs replacement, the column, motor, and module are serviced as a assembly.**

The Electric Power Steering (EPS) module uses input signals received from sensors to vary the current to the electric motor for the desired power steering torque. The boost or assist is variable and speed sensitive, responding to sensors monitoring steering torque, steering wheel speed and angle, and vehicle speed. The steering system is fully integrated with the vehicle's electronic stability control system and helps to compensate in split-traction, torque steer, and pull-drift (crowned road) situations. Communication is received and transmitted to the EPS module on the CAN line.

The EPS module outputs the following actions based on input received:

- **Basic Operation:** Based on vehicle speed, assists the column rotation based on driver input to decrease steering effort for the driver.
- **Variable Servo Steering:** When the speed of the vehicle is increased, the module reduces the amount of assistance to the column.
- **Active Return:** The module commands the motor to quicken the steering wheel in returning to the center position after steering.
- **Damping of Steering Return Oscillations:** After a steering maneuver, the chassis produces oscillations that the module will then use the motor to try and reduce.
- **Selectable Power Assistance:** Instrument panel driver selectable modes vary the level of power steering assistance in three ways: 1) "Comfort" provides a balance of steering feel and steering effort. 2) "Normal" increases steering feel and effort by one level. 3) "Sport" provides the greatest amount of steering feel and

requires the highest of steering effort.

MODULE, ELECTRONIC SHIFT

DESCRIPTION

8 SPEED ESM

The Electronic Shift Module (ESM) is part of the shifter assembly called the E-Shifter. The E-Shifter is an electronic Shift-by-Wire device that is mounted to the vehicle center console. It uses CAN messages to communicate driver requests for transmission gear changes without a mechanical connection. The E-Shifter also provides means for displaying the current/pending transmission gear state via the illuminated PRNDM pattern on the shift knob.

OPERATION

OPERATION

The E-Shifter assembly incorporates an electronic control module called an ESM. The ESM communicates with the TCM and other modules on the Controller Area Network (CAN) C Bus. There is also a CAN DPT (Dedicated Powertrain) bus that is used only by the ESM and TCM. If one CAN bus is faulted, the other CAN bus transmits and receives the information required for uninterrupted operation.

The ESM can set Diagnostic Trouble Codes (DTCs) when a fault is detected. The E-shifter assembly backlighting can also indicate a fault by flashing the gear selection indicator on and off or turning it off completely.

The Electronic Shifter (E-Shifter) offers (P, R, N, D, M) modes of function. The M selection (manual mode) is engaged by moving the shift-lever sideways to M. Requests to up/down shift are achieved by moving the lever fore/aft once in the manual position.

The shifter knob (or handle) is the only serviceable part of the Shifter assembly.

MODULE, FUEL PUMP CONTROL

DESCRIPTION

DESCRIPTION

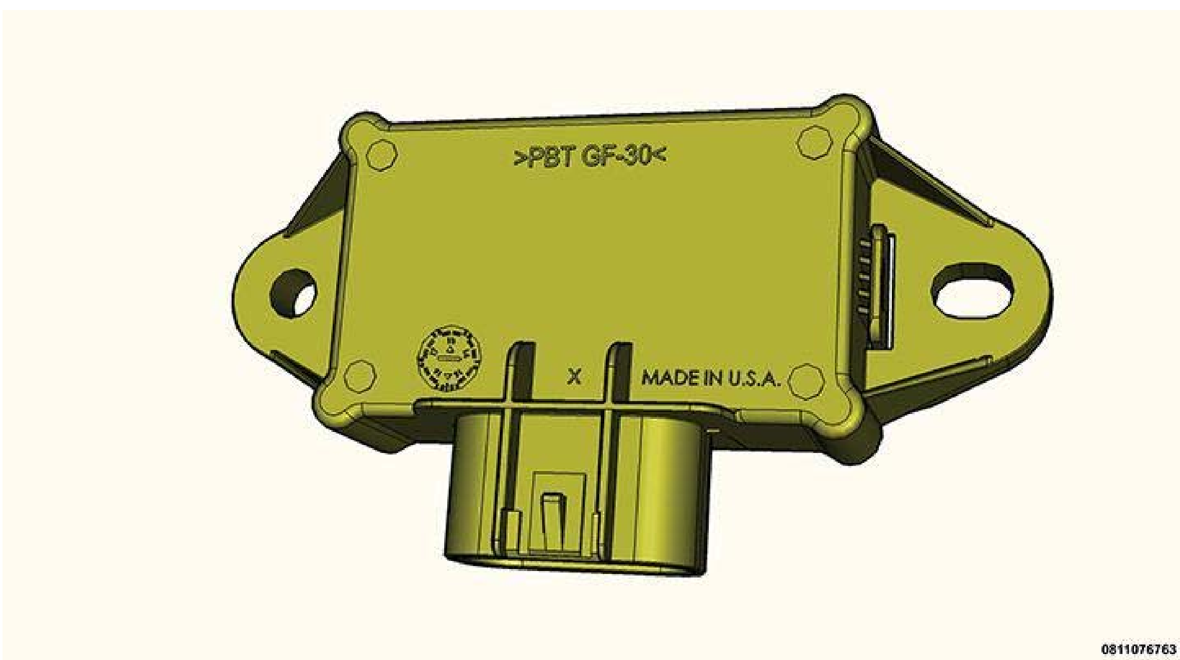

Fig. 31: Fuel Pump Control Module
Courtesy of CHRYSLER GROUP, LLC

The Fuel Pump Control Module (FPCM) is secured to the right inner quarter panel behind the right rear wheel housing in the trunk compartment. The module is concealed behind the trunk side trim.

OPERATION

OPERATION

When the Powertrain Control Module (PCM) receives a 'Start' or 'Run' signal from the ignition; It energizes the Fuel Pump relay which sends a continuous 12 volt supply to the Fuel Pump Control Module (FPCM). The PCM also sends a control signal directly to the FPCM which regulates the Pulse Width Modulated (PWM) signal that will be sent to the Fuel Pump Module. The PWM signal (duty cycle) will vary from 10-100% depending on the input of the Fuel Rail Pressure sensor and other engine demands. The PCM receives a PWM signal from the FPCM representing the state of all inputs and outputs of the FPCM. This is a Constant Pressure Fuel system which means any Delta Pressure test performed on the Fuel Pump would show a continuous pressure (regardless of the changes in PWM). If a pressure sensor fails or other failures are present; The duty cycle goes to Limp mode (100%) to maintain fuel pressure.

REMOVAL

REMOVAL

1. Disconnect and isolate the negative battery cable.
2. Remove the trim from the right quarter inner panel to access Fuel Pump Control Module (FPCM), which is located just behind the right rear wheel house. Refer to CARPET, REMOVAL .

MODULE, HEATED SEAT

DESCRIPTION

DESCRIPTION

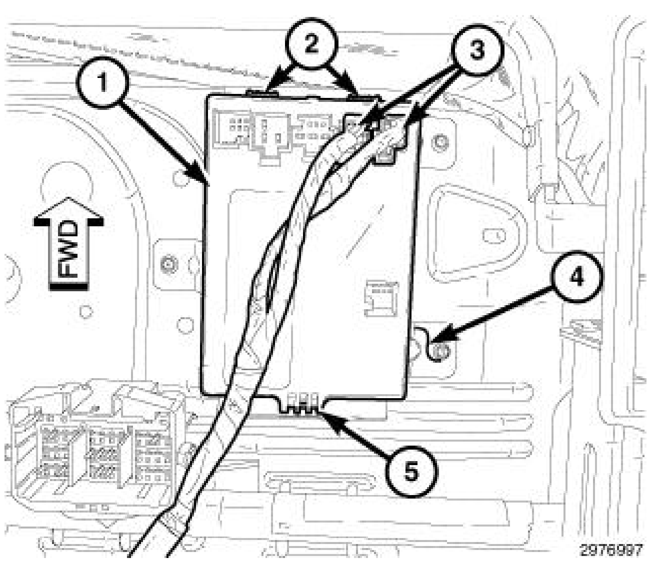

Fig. 34: Electrical Connectors, Heated Seat Module, Retaining Tab & Bracket
Courtesy of CHRYSLER GROUP, LLC

The Heated Seat Module (HSM) is located under the passenger front seat. It has a multiple electrical connectors (CAN + POWER, Front Heat, Front Vent and Heated Steering Wheel connections) and a push pin style retainer that secures it to the seat pan. The module can be accessed from under the passenger seat with the seat in the full back and up position.

The HSM is a CAN-IHS bus microcontroller providing outputs to the power seats, heated seat pads, heated steering wheel, and ventilating up to two seats. The HSM receives commands over the CAN IHS BUS from the BCM. The seat thermistor is hard wired to the HSM.

Heated Seats - The HSM uses a Pulse Width Modulation (PWM) to provide power to the seat cushion and back heating elements. The temperature sensor thermistor is located in the seat cushion. The thermistor sensor feedbacks from each seat heating element to the HSM to regulate the heater outputs to prevent any seat temperature to rise above set points. Seat heating has two selectable heat settings which are HI and LO. Depending on thermistor reading, the HSM will start the heater output by adjusting the PWM heat level according to the calibration table.

Vented Seats - The seat venting has two selectable speeds for the fans. For seat venting, each press of the switch button will cause the seat to change venting modes. The HSM has a single low side control signal to control each vented seat. The HSM does not directly drive the vent motors.

Heated Steering Wheel - The HSM provides power to the steering wheel heating element. The heated steering wheel is standard when the vehicle is equipped with front heated seats. During normal operation, the HSM will switch on the power for the heated wheel only if the engine is running. The heated steering wheel temperature sensor is hardwired to the EVIC (switch) which sends that information over a LIN Bus through the clockspring/SCCM to the BCM. The thermistor sensor feedbacks from the steering wheel heating element via the CAN Internal High Speed (IHS) bus to the HSM regulating the heater output to prevent the wheel temperature to rise above the maximum threshold temperature set point.

OPERATION

OPERATION

The Heated Seat Module (HSM) controls the heated seat system and the Heated Steering Wheel (HSW), when equipped. The HSM is secured to a mounting bracket located under the front passenger seat. The HSM responds to heated seat and steering wheel switch messages and ignition status inputs by controlling the 12 volt Direct Current (DC) output to the seat and steering wheel heating elements through high side drivers.

When either of the front heated seat switches in the U-Connect Touch™ screen module are pressed, the module sends a message over the Controller Area Network (CAN) data bus to the HSM, signaling the HSM to energize the heating elements for the front seat.

When the HSW switch in the U-Connect Touch™ screen module is pressed, the module sends a message over the Controller Area Network (CAN) data bus to the HSM, signaling the HSM to energize the heating element for the steering wheel.

The HSM energizes a high side driver to pulse width modulate the output to the heating elements. Heated seats turn off after approximately 45 minutes of continuous operation. If high-level heating is selected, the control system will remain at the high level for approximately 20 minutes and then drop to the low level. Normal heating

cycle for the heated steering wheel is 52 minutes.

The heated seat and steering wheel system only operate when the engine is running. The heated seat and steering wheel system will turn off automatically whenever the ignition is set to any position other than Run.

The HSM is diagnosed using a scan tool and will automatically turn off the heating elements if it detects an open or low short in a heating element circuit. Refer to **DIAGNOSIS AND TESTING** .

MODULE, HVAC

DESCRIPTION

DESCRIPTION

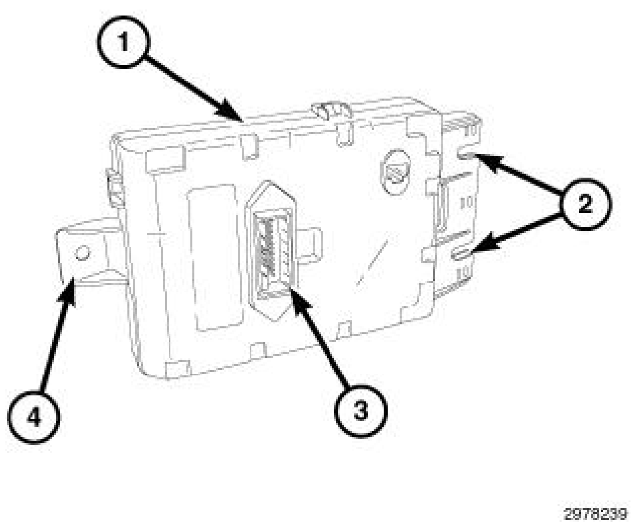

Fig. 37: A/C Heater Module, Mounting Tabs & Connector Receptacle

Courtesy of CHRYSLER GROUP, LLC

The Heating, Ventilation, and Air Conditioning (HVAC) module (1) is a microcontroller designed to operate the heating and A/C system. The HVAC module has a plastic housing with one integral electrical connector receptacle (3) and three mounting tabs (2 and 4).

The HVAC module is located on the air inlet housing, on the passenger side of the vehicle.

OPERATION

OPERATION

The Heating, Ventilation, and Air Conditioning (HVAC) module utilizes integrated circuitry and information carried over the Controller Area Network (CAN) to monitor many sensors and switch inputs throughout the vehicle. In response to those inputs, the internal circuitry and programming of the HVAC module allows it to control electronic functions and features of the HVAC system.

Some of the inputs received by the HVAC module over the CAN are as follows:

- A/C Request
- Ambient Air Temperature
- Electric Back Light (EBL) Request
- Electrical System Voltage
- Engine Coolant Temperature
- Engine Speed
- Humidity, Windshield Glass Temperature and Dewpoint (Automatic Temperature Control)
- Refrigerant Pressure
- Vehicle Identification Number
- Vehicle Odometer

Some of the messages broadcasted by the HVAC module on the CAN are as follows:

- A/C Clutch Engage
- Auto Headlamp Signal
- EBL Status

The HVAC module receives the following information over hardwired circuits:

- Auto Headlamp Signal
- Evaporator Temperature
- Interior Air Temperature
- Left and Right Sun Load

The HVAC module monitors and controls the following over hardwired circuits:

- Driver and Passenger Blend Door Positions
- Blower Motor Speed

- Mode Door Position
- Recirculation Door Position

The HVAC module is diagnosed using a scan tool. Prior to replacing an HVAC module, run the calibration procedure to verify that the concern is not an air door calibration issue. Refer to **STANDARD PROCEDURE** .

The HVAC module cannot be adjusted or repaired and must be replaced if inoperative or damaged.

MODULE, INSTRUMENT PANEL CLUSTER

DESCRIPTION

DESCRIPTION

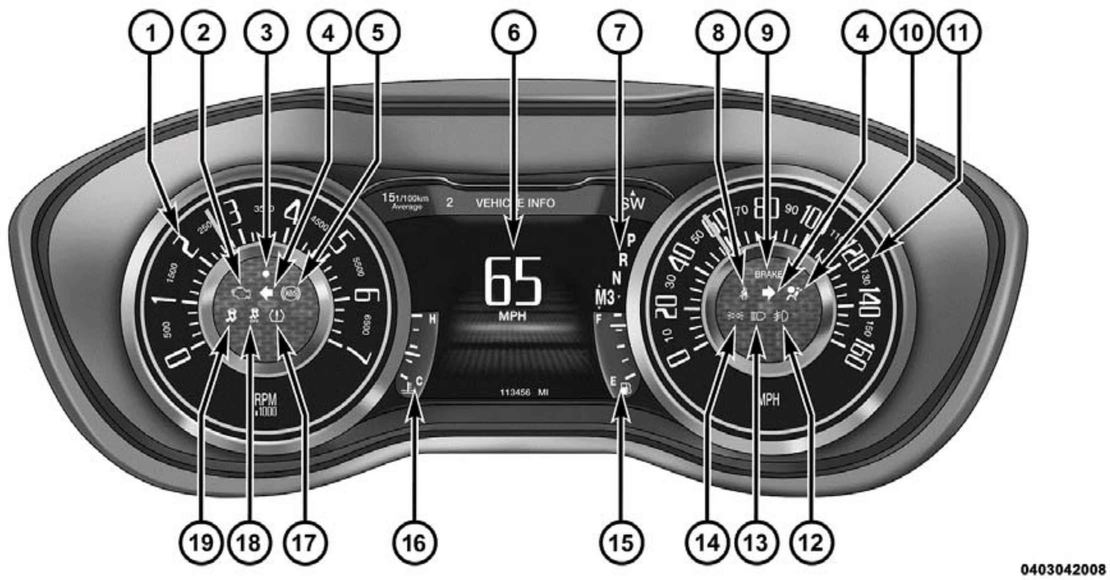

Fig. 40: Instrument Cluster
Courtesy of CHRYSLER GROUP, LLC

The Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) for this vehicle is located directly in front of the driver, above the steering column opening. Only the face of the IC is visible. The remainder of the IC including the mounting provisions and electrical connections are concealed within the instrument panel behind the IC housing and the instrument panel cluster bezel.

The IC gauges and indicators are visible through a dedicated opening in the instrument panel below the cluster hood and are protected by a clear plastic cluster lens. A cluster hood and mask serves as a visor and shields the face of the cluster from ambient light and reflections to reduce glare. The IC has two integral mounting tabs on the sides near the top of the unit as well as two on the bottom which are used to secure the IC to the molded plastic instrument panel cluster carrier with screws.

Besides analog gauges and Light Emitting Diode (LED) unit indicators, the IC incorporates a multicolor Thin Film Transistor (TFT) display unit. The TFT will display odometer information and automatic transmission gear selection. The TFT may also display numerous indications, textual messages, both static and animated graphics and certain diagnostic information, some of which are model and equipment dependent. Refer to **CENTER, ELECTRONIC VEHICLE INFORMATION, DESCRIPTION** .

Several versions of the IC module are offered for this vehicle. These versions accommodate all of the variations of optional equipment and regulatory requirements for the various markets in which the vehicle is offered. The microcontroller-based IC utilizes integrated circuitry and information carried on the Controller Area Network (CAN) data bus along with several hard wired analog and multiplexed inputs to monitor sensors and switches throughout the vehicle. Refer to **COMMUNICATION, DESCRIPTION**.

The IC gauges, indicators and electronic circuitry along with the cluster housing are only serviced as an assembly, and cannot be adjusted or repaired. If a gauge, a LED unit, the TFT display unit, the electronic circuit board and hardware, the cluster overlay or the cluster housing is damaged or ineffective, the entire IC unit must be replaced. The cluster lens and the cluster hood and mask are available for separate service replacement.

OPERATION

OPERATION

The Instrument Panel Cluster (IPC) is designed to allow the vehicle operator to monitor the conditions of many of the vehicle components and operating systems. The gauges and indicators in the IPC provide valuable information about the various standard and optional power trains, fuel and emissions systems, cooling systems, lighting systems, safety systems and many other convenience items. The IPC is installed in the instrument panel so that the operator of the vehicle can view all of these monitors easily, yet still allow relative ease of access for service.

The microcontroller-based IPC hardware and software uses various inputs to control the gauges and indicators visible on the face of the cluster. Some of these inputs are hard wired, but most are in the form of electronic messages that are transmitted by other electronic modules over the Controller Area Network (CAN) data bus. Refer to **COMMUNICATION, OPERATION**.

The IPC microcontroller smooths the input data using algorithms to provide gauge readings that are accurate, stable and responsive to operating conditions. These algorithms are designed to provide gauge readings during normal operation that are consistent with customer expectations. However, when abnormal conditions exist such as high coolant temperature, the algorithm can drive the gauge pointer to an extreme position and the microcontroller can sound a chime warning to provide distinct visual and audible indications of a problem to the vehicle operator. The IPC may also produce audible warnings for other electronic modules in the vehicle based upon electronic chime request messages received over the CAN data bus. Each audible warning is intended to provide the vehicle operator with an audible alert to supplement a visual indication.

The IPC circuitry operates on battery current received through a fused B(+) fuse on a non-switched fused B(+) circuit, and on battery current received through a fused ignition switch output (run-start) fuse on a fused ignition switch output (run-start) circuit. This arrangement allows the IPC to provide some features regardless of the ignition switch position, while other features will operate only with the ignition switch in the ON or START positions. The circuitry is grounded through a ground circuit of the instrument panel wire harness.

The IPC also has a self-diagnostic test capability that tests each of the CAN bus message-controlled functions of the cluster. This test illuminates the appropriate indicators, positions the gauge needles at several predetermined calibration points across the gauge faces and illuminates all segments of the Electronic Vehicle Information Center (EVIC). The EVIC will display the hardware/software version and the CAN Vehicle Maintenance Monitor (VMM) used in the IPC within the Thin Film Transistor (TFT) display unit. Refer to **DIAGNOSIS AND TESTING** .

Cluster Illumination

Instrument cluster illumination is supplied by several Light Emitting Diode (LED) units controlled by the IPC. The illumination intensity of these LED units can be adjusted only when the exterior lighting is turned ON by rotating the panel dimmer switch thumbwheel (down to dim, up to brighten) of the dimmer module to one of five available minor detent positions. The illumination intensity of the LED units is controlled by the IPC circuitry based upon electronic **dimming level** messages received from the Body Control Module (BCM) (also known as the Common Body Controller/CBC) over the Controller Area Network (CAN) data bus. The BCM monitors an input from the headlamp switch and a dimming level input received from the panel dimmer switch of the dimmer module.

The hard-wired headlamp switch and dimmer module inputs to the BCM may be diagnosed using conventional diagnostic methods. However, proper testing of the electronic communication and processing of the IPC and the electronic **dimming level** messages sent by the BCM over the CAN data bus requires the use of a diagnostic scan tool. Refer to the appropriate Diagnostic & Testing article.

Thin Film Transistor Display

The Thin Film Transistor (TFT) display unit is soldered to the IPC electronic circuit board. With the ignition switch in the OFF or ACCESSORY positions, the TFT display is activated when the driver door is opened (Rental Car mode) and deactivated when the driver door is closed.

The illumination intensity of the TFT unit is controlled by the IPC circuitry based upon electronic **dimming level** messages received from the Body Control Module (BCM) (also known as the Common Body Controller/CBC) over the Controller Area Network (CAN) data bus. The BCM monitors an input from the headlamp switch and a dimming level input received from the panel dimmer switch of the dimmer module. The BCM synchronizes the illumination intensity of other display units with that of the unit in the IPC by sending electronic **dimming level** messages to other electronic modules in the vehicle over the CAN data bus.

The IPC TFT display unit has several display capabilities. The TFT unit displays odometer, trip odometer, gear selector indication (PRNDL) for models with an automatic transmission, both static and animated graphics, several warning or reminder indications and various diagnostic information when certain fault conditions exist. Steering wheel mounted switches are used to control some of the display modes of the TFT. Refer to **CENTER, ELECTRONIC VEHICLE INFORMATION, OPERATION** for more information.

The TFT display unit is diagnosed using the IPC self-diagnostic actuator test. Refer to **DIAGNOSIS AND TESTING** . Proper testing of the CAN data bus and the electronic data bus message inputs to the IPC that control some of the TFT display functions requires the use of a diagnostic scan tool. Refer to the appropriate Diagnostic & Testing article. Specific operation details for the odometer, the trip odometer, the gear selector indicator and the various warning and reminder indicator functions of the TFT display unit may be found elsewhere in this service information.

MODULE, KEYLESS IGNITION NODE

DESCRIPTION

DESCRIPTION

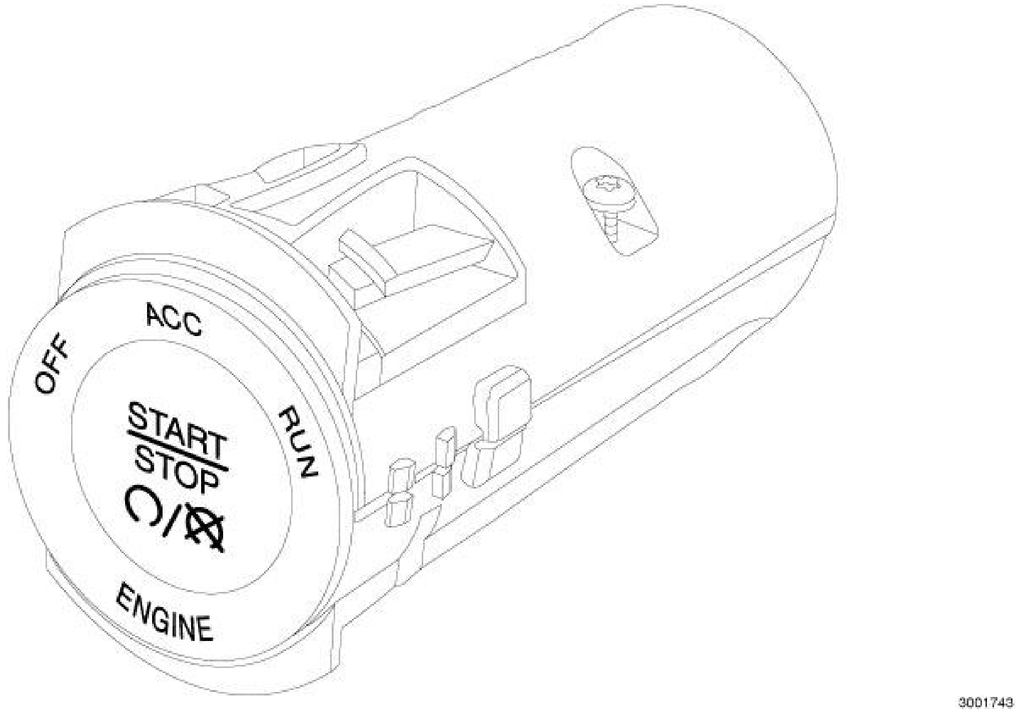

Fig. 43: Keyless Ignition Node (KIN)
Courtesy of CHRYSLER GROUP, LLC

Keyless Ignition Node (KIN) is part of the new ignition system.

The KIN module is located in the instrument panel to the left of the center stack.

OPERATION

OPERATION

The Keyless Go system with the Keyless Ignition Node (KIN) replaces the conventional key and ignition switch with a momentary button press and a wireless electronic key (FOBIK). When the operator presses the GO-Button the FOBIK is interrogated wirelessly. If the FOBIK is recognized as belonging to the vehicle and in the vehicle interior the system allows the ignition state of the vehicle to be manipulated by the operator between the LOCK, ACCESSORY, RUN, and START ignition states. This causes changes in the ignition status signals on the vehicle's CAN-C data buses and hardwired outputs controlled by the starting system master. As far as the vehicle's ignition system is concerned, keyless go control is indiscernible from legacy conventional control using a rotational switch and key.

- When the Go-Button on the KIN is pressed, the Radio Frequency Hub Module (RFHM) is signalled with "request to start".
- The RFHM then uses the LF (low frequency) antennas to communicate with the FOB and confirm the FOB is located inside the vehicle.
- Once located, the FOB's response is evaluated by the RFHM to determine if the person pushing on the Go-Button is in fact the owner. This process completes 'FOB authentication'.
- Once successfully completed, the RFHM next sends the BCM the ignition switch position, which equates to a 'request to start' command.

NOTE: **In case the ignition switch does not change with the push of a button, the RKE**

transmitter may have a low or dead battery. In this situation a back up method can be used to operate the ignition switch. Put the nose side (side opposite of the emergency key) of the Key Fob against the Go-Button and push to operate the ignition switch.

After putting the vehicle into park, pushing the KIN's Go-Button allows the vehicle's engine to be shut off. In an emergency, pressing the Go-Button continuously for 2 seconds or repeatedly (one hit every 30- 500ms) will cause the engine to shut off when vehicle speed is greater than 5 mph.

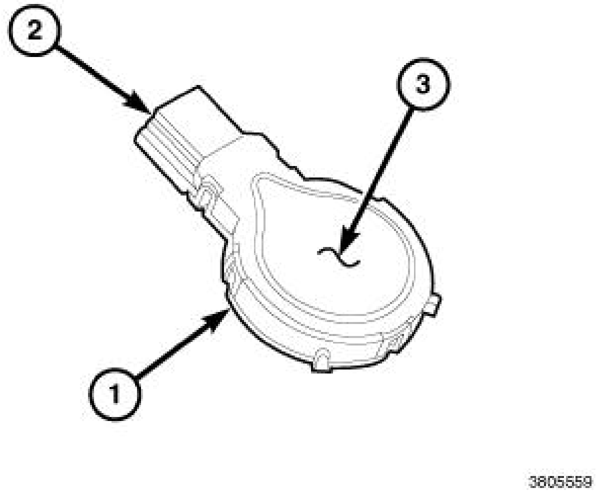
MODULE, LIGHT RAIN SENSOR

DESCRIPTION

DESCRIPTION



[Fig. 47: Light Rain Sensor Module Components]
Courtesy of CHRYSLER GROUP, LLC

The Light Rain Sensor Module (LRSM) (1) is the primary component of the automatic wiper system. The LRSM is also capable of performing an ambient light sensor function; therefore, it is alternately referred to as the Rain Light Sensor Module (RLSM), the Light Sensor Module (LSM), the Rain Light Sensor (RLS) or the Rain Sensor Module (RSM). The LRSM is located on the inside of the windshield glass just below and to the right of the inside rear view mirror mounting button. The LRSM is concealed from view within the vehicle interior by a molded plastic inside rear view mirror bracket trim cover that fits over the top of the LRSM housing and the LRSM mounting bracket, but the LRSM is visible through the windshield glass from the exterior of the vehicle.

The molded black plastic LRSM housing has an integral connector receptacle (2) with three terminal pins. These terminal pins connect the LRSM to the vehicle electrical system through a dedicated take out and connector of the overhead wire harness that extends from above the headliner. The windshield side of the housing is filled with a clear, silicone gelatin (also known as SilGel) adhesive membrane pad (3), which serves as an optical coupler between the sensor and the inside of the windshield glass. A spring steel retaining strap or clip extends forward on each side of the housing to latch the LRSM to a molded black plastic mounting bracket, which is permanently bonded to the inside of the windshield glass.

Concealed and protected within the LRSM housing is the electronic circuitry of the module, which includes an InfraRed (IR) diode and photocell based light and rain sensors, control electronics and Local Interface Network (LIN) data bus communication management hardware. The LRSM is a LIN slave node and communicates over a single LIN bus circuit with the Body Control Module (BCM) (also known as the Common Body Controller/CBC). The BCM is a LIN master node and a gateway to the Controller Area Network (CAN) data bus. The BCM controls the exchange of electronic messages back and forth between the LRSM and other electronic modules in the vehicle, as well as with a diagnostic scan tool connected to the Data Link Connector (DLC).

The LRSM cannot be adjusted or repaired. If ineffective or damaged, the entire module must be replaced. The silicone gelatin adhesive membrane pad is available for separate service replacement. The LRSM mounting

bracket is serviced only as a unit with the windshield glass.

OPERATION

OPERATION

The Light Rain Sensor Module (LRSM) (also known as the Rain Light Sensor Module/RLSM, the Light Sensor Module/LSM, the Rain Light Sensor/RLS or the Rain Sensor Module/RSM) senses moisture and ambient light levels on the outside of the windshield glass and sends electronic messages to the Body Control Module (BCM) (also known as the Common Body Controller/CBC) over the Local Interface Network (LIN) data bus. The BCM relays messages back and forth between the LRSM and other electronic modules in the vehicle.

For the rain sensor function, InfraRed (IR) diodes within the LRSM generate infrared light beams that are aimed by the optics of the sensor through the windshield glass, while an IR photo diode monitors the infrared light reflected back from the windshield glass. When sufficient moisture accumulates within the wipe pattern on the windshield glass, less of the infrared light is reflected back and the sensor detects a change in the monitored infrared light intensity. For the light sensor function, an IR photo diode within the sensor monitors the intensity of the ambient infrared light received through the windshield glass and the sensor optics.

The internal programming of the LRSM sends the appropriate electronic **wipe command** messages to the BCM over the LIN data bus. The BCM then responds by activating or deactivating the wiper system. Similarly, the LRSM provides electronic **ambient light level** messages to the BCM, and the BCM relays these messages to other electronic modules in the vehicle.

The Steering Column Control Module (SCCM) microcontroller sends electronic **wiper switch status** and **automatic wipe sensitivity level** messages over the Controller Area Network (CAN) data bus to the BCM based upon the driver-selected settings of the control knob on the control stalk of the multifunction switch. The higher the selected wipe sensitivity setting the more sensitive the LRSM is to the accumulated moisture on the windshield glass, and the more frequently the LRSM will send **wipe commands** to the BCM to operate the wiper system. The BCM also monitors electronic **automatic display brightness level** messages based upon the driver-selected settings of the Electronic Vehicle Information Center (EVIC) as well as electronic messages from other electronic modules in the vehicle received over the CAN data bus, then relays the messages to the LRSM over the LIN bus.

The LRSM operates on battery current received through a fused ignition output (run) circuit. The LRSM has a path to ground at all times through a take out of the body wire harness with an eyelet terminal that is secured to the body sheet metal. Therefore, the LRSM is operational only when the ignition switch status is On.

If the BCM receives an electronic status message from the LRSM indicating a sensor failure condition, a **Rain Sensor Failure** message should be displayed by the Instrument Cluster (IC) (also known as the Instrument Panel Cluster/IPC). It is important to note that the default operation of the automatic wiper system is continuous wipe On, while the default operation for automatic lighting is On. Therefore, if no command message is received by the BCM from the LRSM for more than about five seconds when the Automatic wipe mode is selected, the wipers will default to Low Speed or High Speed continuous wipe operation. Likewise, if no command message is received by the BCM from the LRSM when the Automatic lighting mode is selected, the exterior lighting will default to On. The BCM must be properly configured for the automatic wipers and automatic lighting options in order for these systems to function.

The hard wired circuits of the LRSM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. However, conventional diagnostic methods

will not prove conclusive in the diagnosis of the LRSM or the electronic controls and communication between other modules and devices that provide some features of the automatic wiper and automatic lighting systems. The most reliable, efficient and accurate means to diagnose the LRSM or the electronic controls and communication related to LRSM operation requires the use of a diagnostic scan tool. Refer to the appropriate Diagnostic & Testing article.

REMOVAL

REMOVAL

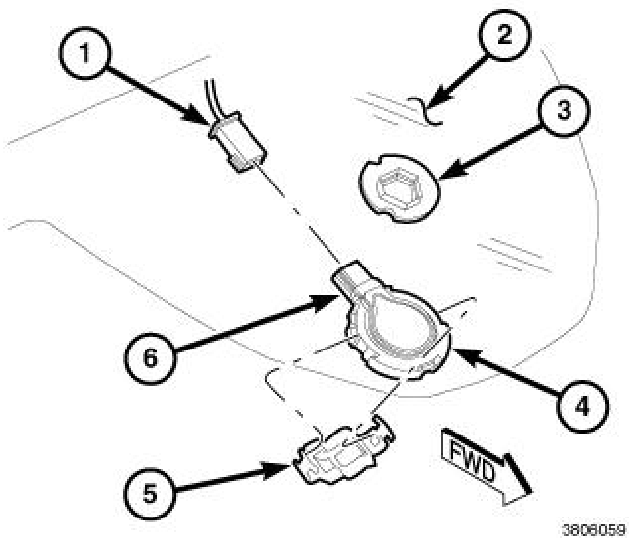


Fig. 48: LRSM, Harness Connector, Mount Bracket & Retaining Strap
Courtesy of CHRYSLER GROUP, LLC

1. Disconnect and isolate the negative cable from the battery. If equipped with an Intelligent Battery Sensor (IBS), disconnect the IBS connector before disconnecting the negative cable from the battery.
2. Remove the inside rear view mirror from the mounting button (3) on the inside of the windshield glass (2). Refer to **MIRROR, REARVIEW, REMOVAL** .
3. Disconnect the wire harness connector (1) from the connector receptacle for the Light Rain Sensor Module (LRSM) (6).
4. Insert the tip of a small screwdriver into the rectangular cutout on one side of the spring steel retaining strap (5) on the LRSM and carefully pry the end of the strap closest to the glass away from the groove in the mounting bracket (4) on the windshield. Now rotate the loose side of the strap away from the glass far enough to disengage the other side of the strap from the mounting bracket groove.
5. Firmly grasp the connector receptacle of the LRSM to pull the module away from the windshield glass and the mounting bracket.
6. If the LRSM will be reinstalled, the silicone gelatin (also known as SilGel) adhesive membrane pad MUST be removed, discarded and replaced with a new unit as described in: **STANDARD PROCEDURE** - Silicone Gelatin Pad Replacement.

INSTALLATION

INSTALLATION

CAUTION: The Light Rain Sensor Module (LRSM) is equipped with a clear, silicone gelatin

(SilGel) adhesive membrane that serves as an optical coupler between the sensor and the windshield glass. Extreme care must be exercised to protect this membrane from contamination before it is installed in the vehicle. The LRSM should always be serviced only in a dust-free environment. Do not touch the membrane with your fingers or tools. The membrane should only come into contact with the clean and dry inside surface of the glass within the mounting bracket bonded to the windshield. If contaminated, clean any foreign material from the windshield glass using rubbing alcohol and a lint-free cloth. A contaminated SilGel membrane will negatively impact LRSM performance.

CAUTION: When installing the Light Rain Sensor Module (LRSM) it is necessary to minimize air pockets trapped between the SilGel membrane and the windshield glass. Excessive air pockets will negatively impact LRSM performance. It is important to adhere to the procedure steps in a deliberate manner to achieve satisfactory results.

CAUTION: To avoid excessive air pockets, do not try to install the spring steel retaining strap until AFTER the Light Rain Sensor Module (LRSM) has been successfully positioned to the glass within the mounting bracket bonded to the windshield.

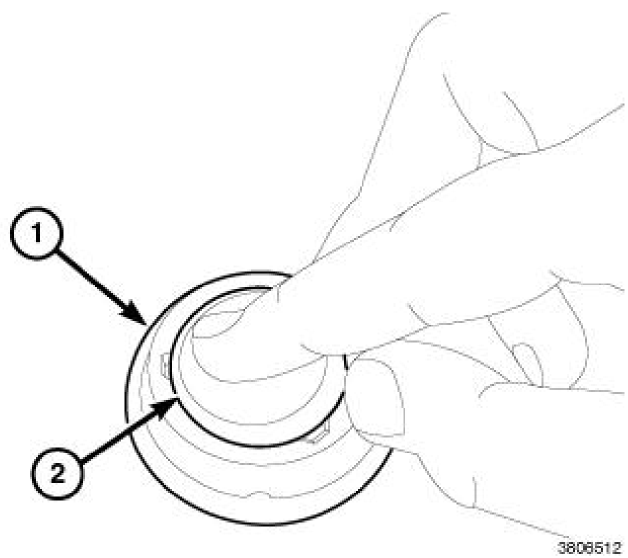

Fig. 49: LRSM & Mounting Bracket
Courtesy of CHRYSLER GROUP, LLC

1. If a new Light Rain Sensor Module (LRSM) is being installed, remove the protective shipping cap from the LRSM as described in: **STANDARD PROCEDURE** - Protective Cap Removal. If an existing LRSM is being reused, the silicone gelatin (also known as SilGel) adhesive membrane pad MUST be removed, discarded and replaced with a new unit as described in: **STANDARD PROCEDURE** - Silicone Gelatin Pad Replacement.
2. Grasp the LRSM (2) by the connector receptacle between your thumb and middle finger. Place your index finger on the back of the LRSM at the point opposite the connector receptacle.
3. Align the LRSM with the mounting bracket (1) bonded onto the inside of the windshield glass near the inside rear view mirror mounting button.
4. Slowly insert the LRSM into the mounting bracket at a slight angle so that the edge of the module nearest

the tip of your index finger makes the initial contact with the windshield glass.

5. Using a slow, deliberate motion and light pressure, draw your index finger across the back of the LRSM toward the connector receptacle until the silicone gelatin adhesive membrane pad is in full contact with the windshield glass.

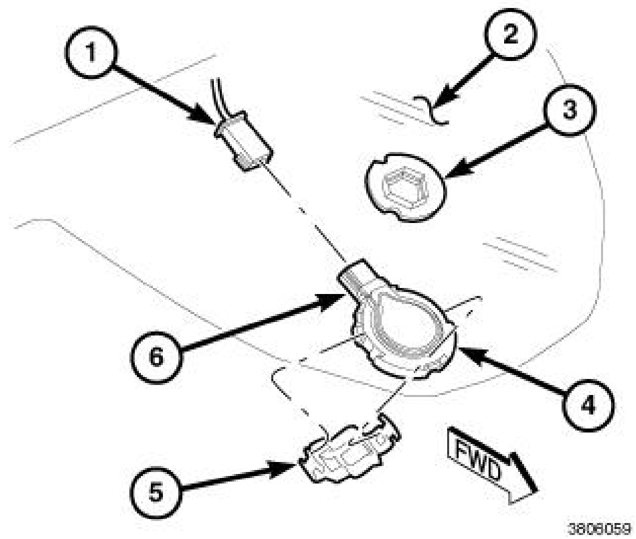

Fig. 50: LRSM, Harness Connector, Mount Bracket & Retaining Strap
Courtesy of CHRYSLER GROUP, LLC

6. Engage one side of the spring steel retaining strap (5) into the groove on one side of the LRSM mounting bracket (4) on the inside of the windshield glass (2).
7. Depress the opposite side of the retaining strap over the LRSM firmly and evenly until it fully engages the groove of the mounting bracket with an audible click.
8. Looking through the windshield from outside the vehicle, inspect the silicone gelatin adhesive membrane pad for air pockets. If air pockets are observed, let the vehicle stand for about four hours at room temperature to allow the air pockets to dissipate. If an adhesive void (air pocket) greater than about 1 millimeter (0.04 inch) is observed, replace the flawed silicone gelatin adhesive membrane pad with a new unit as described in: **STANDARD PROCEDURE** - Silicone Gelatin Pad Replacement.
9. Reconnect the wire harness connector (1) to the LRSM connector receptacle (6).
10. Reinstall the inside rear view mirror to the mounting button (3) on the inside of the windshield glass. Refer to **MIRROR, REARVIEW, INSTALLATION** .
11. Reconnect the negative cable to the battery. If equipped with an Intelligent Battery Sensor (IBS), reconnect the IBS connector.

The Memory Seat Module (MSM) is located underneath the driver seat. The MSM is attached to a bracket by slide and snap fit. The purpose of the MSM is to operate the driver seat motors and the adjustable steering column.

OPERATION

OPERATION

Memory Seat Module

-

Power and Communication

- The Memory Seat Module (MSM) receives battery current through a fuse in the Power Distribution Center (PDC).
- The MSM receives hard-wired input from the hall effect sensors. The hall effect sensors are internal to the motors and are not serviceable.
- The MSM receives bus input from the Body Control Module (BCM).

Drivers power seat with MSM equipped

- The MSM is used to control driver power seat horizontal and vertical movement.
- The MSM is used to control driver lumbar seat horizontal and vertical movement.
- The drivers seat switch has 6 selectable positions. Forward, rearward, Front Up, Front Down, Rear Up, and Rear Down.
- The MSM is responsible for the 12 volt Direct Current (DC) feed and ground path to the power seat adjuster motors and to the other memory system components.
- When the power seat switch is pressed, the MSM received a hardwired resistor value to identify which seat motor(s) are going to be in use.

- The MSM then provides battery level voltage and ground to the appropriate switch output terminals to drive the seat.

Power Tilt and Telescoping Steering Column Adjustment with MSM equipped

- The MSM is used to control driver power steering column tilt and telescoping movement.
- The Steering Column Control Module (SCCM) monitors the tilt switch input.
- When an input is received from the tilt switch at the SCCM, the input is then sent from the SCCM to the Body Control Module (BCM) on the CAN C bus.
- The BCM converts this input from CAN C bus to CAN B bus.
- The BCM send the request over CAN B bus to the MSM for power steering column tilt and telescoping requests.
- The MSM applies battery level voltage and ground to the appropriate steering column motor.

The hard wired inputs for the MSM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the MSM. The most reliable, efficient, and accurate means to diagnose the MSM requires the use of a diagnostic scan tool. Refer to the appropriate Diagnostic & Testing article

REMOVAL

REMOVAL

1. Position the Memory Seat Module (MSM) (2) to the bracket (4) and connect all electrical connectors to the rear of the MSM.

CAUTION: Properly align the Memory Seat Module (MSM) retaining tabs to the bracket, prior to engagement. Failure to follow these instructions may result damage to the MSM retaining tabs.

2. Install the MSM into the bracket and engage the two rear MSM retaining tabs to the bracket.
3. Engage the two front MSM retaining tabs (3 and 5) to the bracket by carefully pulling down on the front of the MSM.
4. Connect all the electrical connectors (1) to the front of the MSM.
5. Install the driver seat. Refer to SEAT, FRONT, INSTALLATION .
6. Connect the negative battery cable.

MODULE PROGRAMMING

POWER SEAT SYSTEM VERIFICATION TEST

PERFORM POWER SEAT SYSTEM VERIFICATION TEST

1. Disconnect all jumper wires and reconnect all previously disconnected components and connectors.
2. Make sure that all accessories are turned off.
3. Make sure that the battery is fully charged.
4. Turn the ignition on.
5. Using a scan tool, record and erase Diagnostic Trouble Codes (DTCs) from all modules.

6. Operate the driver seat in all positions.
7. Turn the ignition off, wait 10 seconds, then turn the ignition on.
8. With the scan tool, read DTCs.

Are the original condition(s) still present or is there DTCs present in any module(s)?

Yes

- The repair is not complete. Perform the appropriate diagnostic procedure for the DTC or symptom that is still present.

No

- The repair is complete.

MODULE, OCCUPANT RESTRAINT

DESCRIPTION

DESCRIPTION

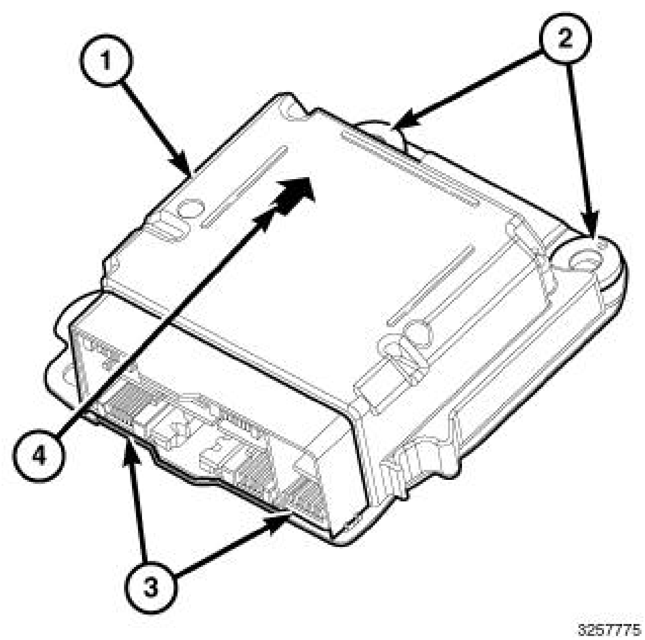

Fig. 54: Occupant Restraint Controller (ORC), Arrow, Integral Mounting Flanges & Electrical Connector Receptacles
Courtesy of CHRYSLER GROUP, LLC

The Occupant Restraint Controller (ORC) (1) is secured by three screws to a stamped steel mounting bracket on the top of the floor panel transmission tunnel near the dash panel and beneath the instrument panel center support in the passenger compartment of the vehicle. Concealed within a hollow in the center of the ORC housing is the electronic circuitry of the ORC which includes a microcontroller, an electronic impact sensor, a rollover sensor, an electronic safing sensor and an energy storage capacitor. A stamped metal cover plate is secured to the bottom of the ORC housing to enclose and protect the internal electronic circuitry and components.

An arrow (4) printed on the label on the top of the ORC housing provides a visual verification of the proper

orientation of the unit, and should always be pointed toward the front of the vehicle. The ORC housing has integral mounting flanges (2) on the right and left front and the left rear corner. The stamped metal cover plate has two integral locating pins on its lower surface. Two molded plastic electrical connector receptacles (3) exit the rearward facing side of the ORC housing. These receptacles connect the ORC to the vehicle electrical system through two dedicated take outs and connectors, one from the instrument panel wire harness and the second from the body wire harness.

The impact sensor and safing sensor internal to the ORC are calibrated for the specific vehicle, and are only serviced as a unit with the ORC. In addition, there are unique versions of the ORC for vehicles with or without certain optional Supplemental Restraint System (SRS) components. The ORC cannot be repaired or adjusted and, if damaged or ineffective, it must be replaced.

OPERATION

OPERATION

The microcontroller within the Occupant Restraint Controller (ORC) contains the Supplemental Restraint System (SRS) logic circuits and controls all of the SRS components. The ORC uses On-Board Diagnostics (OBD) and can communicate with other electronic modules in the vehicle as well as with the diagnostic scan tool using the Controller Area Network (CAN) data bus. This method of communication is used for control of the airbag indicator in the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) and for SRS diagnosis and testing through the 16-way data link connector located on the driver side lower edge of the instrument panel.

The ORC microcontroller continuously monitors all of the SRS electrical circuits to determine the system readiness. If the ORC detects a monitored system fault, it sets an active and stored Diagnostic Trouble Code (DTC) and sends electronic messages to the IC over the CAN data bus to turn On the airbag indicator. An active fault only remains for the duration of the fault, or in some cases for the duration of the current ignition cycle, while a stored fault causes a DTC to be stored in memory by the ORC. For some DTCs, if a fault does not recur for a number of ignition cycles, the ORC will automatically erase the stored DTC. For other internal faults, the stored DTC is latched forever.

The ORC receives battery current through two circuits; a fused ignition switch output (run) circuit through a fuse in the rear Power Distribution Center (PDC) and a fused ignition switch output (run-start) circuit through a second fuse in the rear PDC. The ORC receives ground through a ground circuit and take out of the instrument panel wire harness that is secured by a ground screw to the body sheet metal. These connections allow the ORC to be operational whenever the status of the ignition switch is Start or On.

The ORC also contains an energy-storage capacitor. When the ignition switch status is Start or On, this capacitor is continually being charged with enough electrical energy to deploy the SRS components for up to one second following a battery disconnect or failure. The purpose of the capacitor is to provide backup SRS protection in case there is a loss of battery current supply to the ORC during an impact.

Various sensors within the ORC are continuously monitored by the ORC logic. These internal sensors, along with several external impact sensor inputs allow the ORC to determine both the severity of an impact and to verify the necessity for deployment of any SRS components. Two remote front impact sensors are located on the back of the right and left vertical members of the radiator support near the front of the vehicle. The electronic impact sensors are accelerometers that sense the rate of vehicle deceleration, which provides verification of the direction and severity of an impact.

The ORC also monitors inputs from the seat track position sensors, seat belt switches, an internal rollover sensor and six additional remote side impact sensors located on the left and right front door module carriers, on the right and left lower B-pillars and on the right and left C-pillars near the belt line to control deployment of the side curtain airbag units and seat (also known as pelvic and thorax) airbags. On vehicles so equipped, the ORC also uses the passenger side seat belt switch input along with an input from the Occupant Detection Sensor (ODS) in the passenger front seat cushion to support the passenger belt alert feature, and will send electronic messages to the IC to illuminate the seat belt indicator when appropriate.

The impact sensors within the ORC are electronic accelerometer sensors that provide an additional logic input to the ORC microcontroller. These sensors are used to verify the need for a SRS component deployment by detecting impact energy of a lesser magnitude than that of the primary electronic impact sensors, and must exceed a safing threshold in order for the SRS components to deploy. On vehicles equipped with side curtain airbags or seat airbags, a separate impact sensor within the ORC provides confirmation to the ORC microcontroller of side impact forces. This separate sensor is a bi-directional unit that detects impact forces from either side of the vehicle.

Pre-programmed decision algorithms in the ORC microcontroller determine when the deceleration rate as signaled by the impact sensors indicate an impact that is severe enough to require SRS protection and, based upon the severity of the monitored impact, determines the level of front airbag deployment force required for each front seating position. When the programmed conditions are met, the ORC sends the proper electrical signals to deploy the dual multistage front airbags at the programmed force levels, the front seat belt tensioners and, if the vehicle is so equipped, the seat airbags and either side curtain airbag unit.

The hard wired inputs and outputs for the ORC may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the ORC or the electronic controls and communication between other modules and devices that provide some features of the SRS. The most reliable, efficient and accurate means to diagnose the ORC or the electronic controls and communication related to SRS operation requires the use of a diagnostic scan tool and may also require the use of the SRS Load Tool special tool along with the appropriate Load Tool Jumpers and Adapters. Refer to the appropriate Diagnostic & Testing article.

REMOVAL

REMOVAL

WARNING: To avoid serious or fatal injury on vehicles equipped with side curtain airbags, disable the Supplemental Restraint System (SRS) before attempting any Occupant Restraint Controller (ORC) diagnosis or service. The ORC may contain a rollover sensor, which enables the system to deploy the side SRS components in the event of a vehicle rollover event. If an ORC containing a rollover sensor is accidentally rolled during service while still connected to battery power, the side SRS components will deploy. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.

WARNING: To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel

component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.

WARNING: **To avoid serious or fatal injury, never strike or drop the Occupant Restraint Controller (ORC), as it can damage the impact sensor or affect its calibration. The ORC contains the impact sensor, which enables the system to deploy the Supplemental Restraint System (SRS) components. If an ORC is accidentally dropped during service, the module must be scrapped and replaced with a new unit. Failure to observe this warning could result in accidental, incomplete, or improper SRS component deployment.**

4. If equipped with a floor shifter:
   a. Disconnect the wire harness connectors from the shifter.
   b. Remove the four nuts that secure the shifter to the weld studs on the floor panel transmission tunnel.
   c. Remove the shifter from the transmission tunnel. If it is a cable-type shifter, carefully position the

shifter and cable out of the way over the right side of the transmission tunnel.

5. Remove the switch bank and bezel from the instrument panel center stack. Refer to **POD, SWITCH BANK, REMOVAL** .
6. Disconnect the instrument panel and body wire harness (3) connectors from the Occupant Restraint Controller (ORC) (1) connector receptacles located on the rearward facing side of the module.
7. Reach through the instrument panel center stack openings to access and cut the sound deadening material along the right side of the ORC.
8. Reach around and behind the left side of the instrument panel center stack support structure to access and cut the sound deadening material along the forward-facing side of the ORC.
9. Pull the sound deadening material over the left side of the ORC far enough to access the mounting provisions.
10. Remove the three screws (2) that secure the ORC to the top of the floor panel transmission tunnel.
11. Remove the ORC from the vehicle.

Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.

WARNING: To avoid serious or fatal injury, never strike or drop the Occupant Restraint Controller (ORC), as it can damage the impact sensor or affect its calibration. The ORC contains the impact sensor, which enables the system to deploy the Supplemental Restraint System (SRS) components. If an ORC is accidentally dropped during service, the module must be scrapped and replaced with a new unit. Failure to observe this warning could result in accidental, incomplete, or improper SRS component deployment.

1. Carefully position the Occupant Restraint Controller (ORC) (1) onto the floor panel transmission tunnel (4). When the ORC is correctly positioned, the orientation arrow on the ORC label will be pointed forward in the vehicle.
2. Install and tighten the three screws (2) that secure the ORC to the floor panel transmission tunnel. Tighten the screws to **SPECIFICATIONS** .
3. Restore the flap of sound deadening material that was cut during the removal procedure over and around the ORC.
4. Reconnect the instrument panel and body wire harness (3) connectors to the ORC connector receptacles located on the rearward facing side of the module. Be certain that the latches and the locks on both connectors are each fully engaged.
5. Reinstall the switch bank and bezel into the instrument panel center stack. Refer to **POD, SWITCH BANK, INSTALLATION** .
6. If equipped with a floor shifter:
   a. Position the shifter over the four weld studs on the top of the floor panel transmission tunnel.
   b. Install and tighten the four nuts that secure the shifter to the weld studs on the floor panel transmission tunnel. Tighten the nuts securely.
   c. Reconnect the wire harness connectors to the shifter.
7. Reinstall the console floor duct onto the floor panel transmission tunnel. Refer to **DUCT, FLOOR CONSOLE, INSTALLATION** .
8. Reinstall the center console onto the top of the floor panel transmission tunnel. Refer to **CONSOLE, FLOOR, INSTALLATION** .
9. Do not reconnect the negative cable to the battery at this time. The Supplemental Restraint System (SRS) Verification Test procedure should be performed following service of any SRS component. Refer to **STANDARD PROCEDURE** .

MODULE, PARK ASSIST

DESCRIPTION

DESCRIPTION

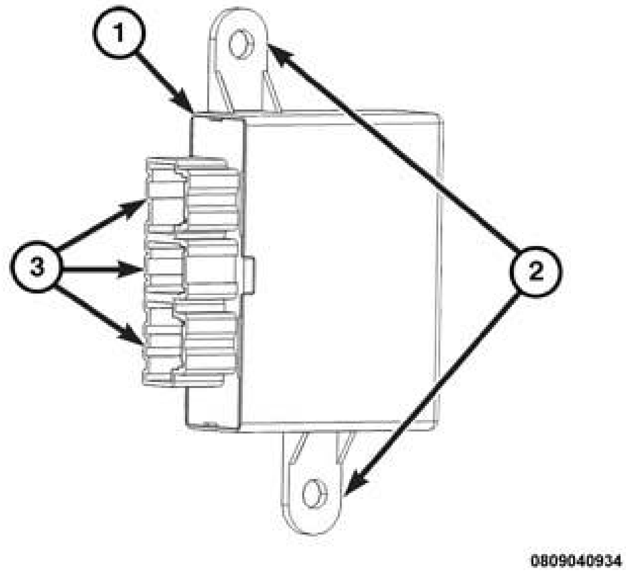

Fig. 57: Park Assist Module, Connector Receptacles & Mounting Tabs
Courtesy of CHRYSLER GROUP, LLC

The Park Assist Module (PAM) (also known as the ParkTronic System/PTS module) (1) is secured to the right inner quarter panel behind the right rear wheel housing in the trunk compartment. One of the two mounting tabs (2) integral to the module housing is inserted into a stamped pocket in the inner quarter panel, while the other mounting tab is secured with a push-in plastic fastener. The module is concealed behind the trunk side trim. Concealed within the molded plastic PAM housing is a microcontroller and the other electronic circuitry of the module. The module housing is sealed to enclose and protect the internal electronic circuitry. The module software is flash programmable.

Three connector receptacles (only two are used for this application) (3) containing terminal pins are integral to the forward-facing side of the housing. The module is connected to the vehicle electrical system through two dedicated take outs and connectors of the body wire harness.

The PAM cannot be adjusted or repaired and, if damaged or ineffective, it must be replaced with a new unit.

OPERATION

OPERATION

The microcontroller within the Park Assist Module (PAM) (also known as the ParkTronic System/PTS module) contains the park assist system logic circuits. The PAM uses On-Board Diagnostics (OBD) and can communicate with other electronic modules in the vehicle as well as with the diagnostic scan tool using the Controller Area Network (CAN) data bus. This method of communication is also used for park assist system diagnosis and testing through the 16-way data link connector located on the driver side lower edge of the instrument panel.

The PAM provides source current to the four park assist sensors located on the back of the rear bumper fascia. The PAM then monitors return inputs from each of the sensors on dedicated hard wired data communication circuits. These sensor inputs allow the PAM to determine when an obstacle is in the rear path of the vehicle, to calculate the relative location of the obstacle and to determine whether the distance to that obstacle is increasing

or decreasing.

Pre-programmed decision algorithms and calibrations allow the PAM microcontroller to determine the appropriate park assist system outputs based upon the inputs received from the park assist sensors and electronic messages received from other modules in the vehicle over the CAN data bus. When the programmed conditions are met, the PAM sends electronic messages to the Instrument Cluster (IC) (also known as the Common Instrument Cluster/CIC) and the Radio Receiver Module (RRM) (also known as the radio or the head unit) over the CAN data bus to obtain the proper park assist system visual and audible outputs.

The PAM microcontroller continuously monitors all of the park assist system electrical circuits and components to determine the system readiness. If a monitored system fault is detected, the PAM sets a Diagnostic Trouble Code (DTC) and sends the appropriate electronic messages to the IC to control the display of the appropriate park assist system graphics and textual messages in the Electronic Vehicle Information Center (EVIC) display within the IC and the generation of the appropriate audible warnings by the RRM.

The PAM receives battery current on a fused ignition output (run) circuit through the Body Control Module (BCM). The PAM has a path to ground at all times through a ground circuit and take out of the body wire harness that is secured to the body sheet metal. These connections allow the PAM to be operational whenever the status of the ignition switch is On.

The hard wired circuits between components related to the PAM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the PAM or the electronic controls and communication between modules and other devices that provide some features of the park assist system. The most reliable, efficient and accurate means to diagnose the PAM or the electronic controls and communication related to park assist system operation requires the use of a diagnostic scan tool.

REMOVAL

REMOVAL

1. Disconnect and isolate the negative cable from the battery. If equipped with an Intelligent Battery Sensor (IBS), disconnect the IBS connector before disconnecting the negative cable from the battery.
2. Remove the trim from the right quarter inner panel to access the Park Assist Module (PAM) (3), which is located just behind the right rear wheel house. Refer to CARPET, REMOVAL .
3. Disconnect the body wire harness connectors (1) from the PAM connector receptacles.
4. Remove the push-pin type retainer (2) that secures the PAM to the quarter inner panel.
5. Slide the PAM upward far enough to disengage the lower mounting tab from the stamped pocket (4) in the right quarter inner panel.
6. Remove the PAM from the vehicle.

1. Position the Park Assist Module (PAM) (3) to the right quarter inner panel above and behind the right rear wheel house. Be certain to engage the lower mounting tab into the stamped pocket (4) in the right quarter inner panel.
2. Reinstall the push-pin type retainer (2) that secures the PAM to the right quarter inner panel.
3. Reconnect the body wire harness connectors (1) to the PAM connector receptacles.
4. Reinstall the trim onto the right quarter inner panel. Refer to CARPET, INSTALLATION .
5. Reconnect the negative cable to the battery. If equipped with an Intelligent Battery Sensor (IBS), reconnect the IBS connector.

MODULE, POWERTRAIN CONTROL

DESCRIPTION

POWERTRAIN CONTROL MODULE

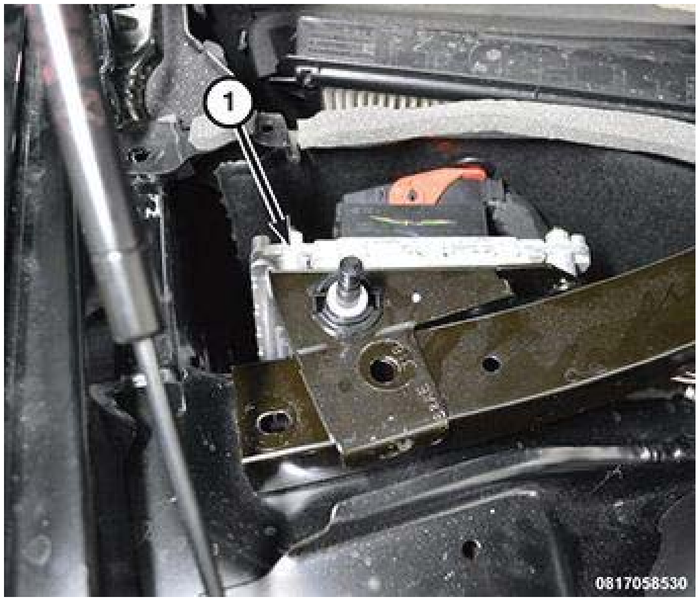

Fig. 60: Powertrain Control Module
Courtesy of CHRYSLER GROUP, LLC

The Powertrain Control Module (PCM) is a pre -programmed, microprocessor digital computer. The PCM operates the fuel system, regulates ignition timing, air-fuel ratio, emission control devices, charging system, certain transmission features, speed control, air conditioning compressor clutch engagement and idle speed. The PCM can adapt its programming to meet changing operating conditions. It also receives input signals from various switches and sensors. Based on these inputs, the PCM regulates various engine and vehicle operations through different system components. These components are referred to as PCM Outputs.

The PCM will operate in two different modes: Open Loop and Closed Loop. During Open Loop operation, the PCM still receives all input signals but, responds only to a limited amount of inputs based on the algorithms for output control. Inputs from the Oxygen (O2) Sensors and other sensors (depending on the PCM programming) are not monitored during Open Loop modes. During Closed Loop operation, the PCM will monitor all inputs and outputs. These inputs indicate to the PCM whether or not the calculated output settings results in the ideal air-fuel ratio. This ratio is 14.7 parts air-to-1 part fuel. By monitoring the exhaust oxygen content through the O2 Sensor and all other inputs, the PCM has the ability to fine tune the air handling, fuel control, ignition timing and spark advance settings. This is done to achieve optimum fuel economy combined with low emission engine performance.

NOTE:	**Depending on vehicle build configuration, transmission and engine type the PCM will be programed with different software to meet the vehicle system needs. It is always important to verify the vehicle`s VIN number and software level in the PCM when diagnosing concerns related to the PCM.**

OPERATION

MODES OF OPERATION

As input signals to the Powertrain Control Module (PCM) change, the PCM adjusts its response to the output devices. For example, the PCM must calculate different injector pulse width and ignition timing for idle than it does for wide open throttle (WOT).

The PCM will operate in two different modes: **Open Loop and Closed Loop** .

During Open Loop modes, the PCM receives input signals and responds only according to preset PCM programming. Input from the oxygen (O2S) sensors is not monitored during Open Loop modes.

During Closed Loop modes, the PCM will monitor the oxygen (O2S) sensors input. This input indicates to the PCM whether or not the calculated injector pulse width results in the ideal air-fuel ratio. This ratio is 14.7 parts air-to-1 part fuel. By monitoring the exhaust oxygen content through the O2S sensor, the PCM can fine tune the injector pulse width. This is done to achieve optimum fuel economy combined with low emission engine performance.

The fuel injection system has the following modes of operation:

- Ignition switch ON
- Engine start-up (crank)
- Engine warm-up
- Idle
- Cruise
- Acceleration
- Deceleration
- Wide open throttle (WOT)
- Ignition switch OFF

The ignition switch On, engine start-up (crank), engine warm-up, acceleration, deceleration and wide open throttle modes are Open Loop modes. The idle and cruise modes, (with the engine at operating temperature) are Closed Loop modes.

IGNITION SWITCH (KEY-ON) MODE

This is an Open Loop mode. When the fuel system is activated by the ignition switch, the following actions occur:

- The PCM determines atmospheric air pressure from the MAP sensor input to determine basic fuel strategy.
- The PCM monitors the engine coolant temperature sensor input. The PCM modifies fuel strategy based on this input.
- Intake manifold air temperature sensor input is monitored.
- Throttle position sensors (TPS) and pedal value sensors are monitored.
- The auto shutdown (ASD) relay is energized by the PCM for approximately three seconds.
- The fuel pump is energized through the fuel pump relay by the PCM. The fuel pump will operate for approximately three seconds unless the engine is operating or the starter motor is engaged.
- The O2S sensor heater element is energized via the O2S heater drivers (solid state devices) internal to the PCM. These drivers provide a PWM 0-12V signal to heat the O2S heater elements to optimize the O2S sensor signal output. The O2S sensor input is not used by the PCM to calibrate air-fuel ratio during this mode of operation.

ENGINE START-UP MODE

This is an Open Loop mode. The following actions occur when the starter motor is engaged.

The PCM receives inputs from:

- Direct Battery voltage
- Accelerator Pedal Position Sensor (APPS)
- Engine Coolant Temperature (ECT) sensor
- Crankshaft Position (CKP) sensor
- Intake Manifold Air Temperature (IMAT) sensor
- Manifold absolute pressure (MAP) sensor
- Throttle position sensors (TPS)
- Camshaft Position Sensor (CPS) signal

The PCM monitors the crankshaft position sensor. If the PCM does not receive a crankshaft position sensor signal within approximately 3 seconds of cranking the engine, it will shut down the fuel injection system.

The fuel pump is activated by the PCM through the fuel pump relay located in the front Power Distribution Center (PDC).

Voltage is applied to the fuel injectors with the ASD relay via the PCM. The PCM will then control the injection sequence and injector pulse width by actuating ground circuit to each individual injector on and off.

The PCM determines the proper ignition timing according to input received from the crankshaft position sensor.

ENGINE WARM-UP MODE

This is an Open Loop mode. During engine warm-up, the PCM receives inputs from:

- Direct Battery voltage
- Crankshaft Position (CKP) sensor
- Engine Coolant Temperature (ECT) sensor
- Intake Manifold Air Temperature (MAT) sensor
- Manifold Absolute Pressure (MAP) sensor
- Throttle Position Sensors (TPS)
- Camshaft Position Sensor (CPS) signal
- Park/neutral switch (gear indicator signal)
- Accelerator Pedal Position Sensor (APPS)
- Air conditioning select signal (if equipped)
- Air conditioning request signal (if equipped)

Based on these inputs the following occurs:

- Voltage is applied to the fuel injectors with the ASD relay via the PCM. The PCM will then control the injection sequence and injector pulse width by turning the ground circuit to each individual injector on and off.
- The PCM adjusts engine idle speed through the electronic throttle control (ETC) motor and adjusts ignition

timing accordingly.

- The PCM operates the A/C compressor clutch through the clutch relay. This is done if A/C has been selected by the vehicle operator and requested by the A/C thermostat.
- When the heating element has reached operating temperature located in the O2S, the PCM will begin monitoring O2 sensor output readings. The system will then leave the warm-up (open loop) mode and go into closed loop operation.

IDLE MODE

When the engine is at operating temperature, this is a Closed Loop mode. At idle speed, the PCM receives inputs from:

- Air conditioning select signal (if equipped)
- Air conditioning request signal (if equipped)
- Battery voltage
- Camshaft Position Sensor (CPS) signal
- Engine Coolant Temperature (ECT) sensor
- Intake Manifold Air Temperature (MAT) sensor
- Manifold absolute pressure (MAP) sensor
- Accelerator Pedal Position Sensor (APPS)
- Throttle position sensors (TPS)
- Crankshaft Position (CKP) sensor
- Battery voltage
- Park/neutral switch (gear indicator signal)
- Oxygen (O2) sensors

Based on these inputs, the following occurs:

- Voltage is applied to the fuel injectors with the ASD relay via the PCM. The PCM will then control injection sequence and injector pulse width by turning the ground circuit to each individual injector on and off.
- The PCM monitors the O2S sensor input and adjusts air-fuel ratio by varying injector pulse width. It also adjusts engine idle speed through the electronic throttle control (ETC) motor.
- The PCM adjusts ignition timing by increasing and decreasing spark advance.
- The PCM operates the A/C compressor clutch through the A/C clutch relay. This happens if A/C has been selected by the vehicle operator and requested by the A/C thermostat.

CRUISE MODE

When the engine is at operating temperature, this is a Closed Loop mode. At cruising speed, the PCM receives inputs from:

- Air conditioning select signal (if equipped)
- Air conditioning request signal (if equipped)
- Battery voltage

- Camshaft Position Sensor (CPS) signal
- Engine Coolant Temperature (ECT) sensor
- Intake Manifold Air Temperature (MAT) sensor
- Manifold absolute pressure (MAP) sensor
- Accelerator Pedal Position Sensor (APPS)
- Throttle position sensors (TPS)
- Crankshaft Position (CKP) sensor
- Battery voltage
- Park/neutral switch (gear indicator signal)
- Oxygen (O2) sensors

Based on these inputs, the following occurs:

- Voltage is applied to the fuel injectors with the ASD relay via the PCM. The PCM will then adjust the injector pulse width by turning the ground circuit to each individual injector on and off.
- The PCM monitors the O2S sensor input and adjusts air-fuel ratio.
- The PCM adjusts ignition timing by turning the ground path to the coils on and off.
- The PCM operates the A/C compressor clutch through the clutch relay. This happens if A/C has been selected by the vehicle operator and requested by the A/C thermostat.

ACCELERATION MODE

This is an Open Loop mode. The PCM recognizes an abrupt increase in throttle position or MAP pressure as a demand for increased engine output and vehicle acceleration. The PCM increases injector pulse width in response to increased throttle opening.

DECELERATION MODE

When the engine is at operating temperature, this is an Open Loop mode. During hard deceleration, the PCM receives the following inputs.

- Air conditioning select signal (if equipped)
- Air conditioning request signal (if equipped)
- Battery voltage
- Camshaft Position Sensor (CPS) signal
- Engine Coolant Temperature (ECT) sensor
- Intake Manifold Air Temperature (MAT) sensor
- Manifold absolute pressure (MAP) sensor
- Accelerator Pedal Position Sensor (APPS)
- Throttle position sensors (TPS)
- Crankshaft Position (CKP) sensor
- Battery voltage
- Park/neutral switch (gear indicator signal)
- Oxygen (O2) sensors

- Vehicle speed

If the vehicle is under hard deceleration with the proper RPM and closed throttle conditions, the PCM will ignore the oxygen sensor input signal. The PCM will enter a fuel cut-off strategy in which it will not supply a ground to the injectors. If a hard deceleration does not exist, the PCM will determine the proper injector pulse width and continue injection.

The PCM adjusts ignition timing by turning the ground path to the coils on and off.

WIDE OPEN THROTTLE MODE

This is an Open Loop mode. During wide open throttle operation, the PCM receives the following inputs.

- Battery voltage
- Crankshaft Position (CKP) sensor
- Engine Coolant Temperature (ECT) sensor
- Intake Manifold Air Temperature (MAT) sensor
- Manifold absolute pressure (MAP) sensor
- Accelerator Pedal Position Sensor (APPS)
- Throttle position sensors (TPS)
- Camshaft Position Sensor (CPS) signal

During wide open throttle conditions, the following occurs:

- Voltage is applied to the fuel injectors with the ASD relay via the PCM. The PCM will then control the injection sequence and injector pulse width by turning the ground circuit to each individual injector on and off. The PCM ignores the oxygen sensor input signal and provides a predetermined amount of additional fuel. This is done by adjusting injector pulse width.
- The PCM adjusts ignition timing by turning the ground path to the coil on and off.

IGNITION SWITCH OFF MODE

When ignition switch is turned to OFF position, the PCM stops operating the injectors, ignition coil, ASD relay and fuel pump relay.

6. Position the front cowl top panel (1) to the right rear corner of the engine compartment.
7. Install the two push-pins (2) that secure the front cowl top panel.

8. Connect the negative battery cable.

NOTE: **If a new PCM is installed, it must be programed with the original Vehicle Identification Number (VIN) and mileage. If this is not done, a Diagnostic Trouble Code (DTC) may set.**

NOTE: **If a new PCM is installed. Refer to MODULE, POWERTRAIN CONTROL, MODULE PROGRAMMING.**

9. If a new PCM is being installed, use a scan tool and program the new PCM with the original VIN and vehicle mileage.

MODULE PROGRAMMING

GAS

This procedure is required when one or more of the following situations are true:

- A Powertrain Control Module (PCM) has been replaced.
- Diagnostic Trouble Code (DTC) P1602 - PCM Not Programmed is set.
- An updated calibration or software release is available for either the PCM or Transmission Control Module (TCM).

This procedure assumes that the scan tool is properly configured to the dealership network with either a wired or wireless connection. For help on how to network the scan tool, use the "Help" tab at the top of the diagnostic application.

Programming Procedure

- Using the scan tool:

1. Verify that the scan tool operating software is programmed with the latest software release.
2. Flash the Powertrain Control Module (PCM)
3. From the "Home" screen, select "ECU View"
4. Select "PCM"
5. Select "Misc functions"
    1. Select "Check PCM VIN" and follow the on screen instructions. When complete, select "Finish".
    2. Select "Learn ETC" and follow the on screen instructions. When complete, select "Finish".
    3. Select "Check PCM Odometer" and follow the on screen instructions. When complete, select "Finish".

NOTE: **Due to the PCM/TCM programming procedure, a DTC may be set in other ECUs within the vehicle. Some DTCs may cause the MIL to illuminate. From the "Home" screen select "System View". Then select "All DTCs". Press "Clear All Stored DTCs" if there are any DTCs shown on the list.**

MODULE, POWER SUNROOF

DESCRIPTION

DESCRIPTION

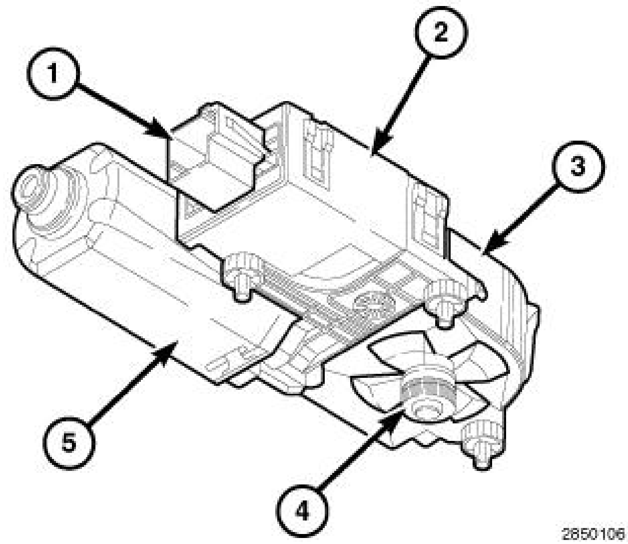

Fig. 67: Single Pane Sunroof Motor Assembly
Courtesy of CHRYSLER GROUP, LLC

The single pane sunroof has a single motor (5) and electronic module unit (2) secured by three screws near the center of the underside of the rear sunroof frame member where it is concealed above the headliner. The motor is a reversible, 12-volt Direct Current (DC) permanent magnet motor with internal thermal protection. The motor is connected mechanically to the sunroof drive gear (4) through a right angle drive and gear reduction transmission (3). The motor also is connected electrically to the on-board electronic control unit that includes an integral connector receptacle (1) that connects the unit to the vehicle electrical system through a dedicated take out and connector of the sunroof wire harness.

The sunroof motor and electronic module units cannot be repaired. If ineffective or damaged, the entire motor and module unit must be replaced.

OPERATION

OPERATION

The single pane power sunroof motor is completely controlled by the circuitry of the on-board electronic module. The module receives battery current on a fused B(+) circuit from the Body Control Module (BCM) and has a path to ground at all times through a take out and eyelet terminal connector secured by a ground screw to the body sheet metal. These connections allow the module to function regardless of the ignition switch position.

However, the module also monitors an input on a fused ignition switch output (run - accessory) circuit, and provides a source current to the sunroof switches in the overhead console only when the ignition switch is in the ON or ACCESSORY positions, or while the accessory delay feature is active. The module then monitors a separate input circuit for each switch position, which it uses to determine the proper outputs to the power sunroof motor. A positive and negative battery connection to the two motor brushes will cause the power sunroof motor to rotate in one direction. Reversing the current through these same two brushes will cause the motor to rotate in the opposite direction.

The hard wired circuits of the power sunroof motor as well as those between the electronic module and the switch

in the overhead console may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the electronic module integral to the power sunroof motor. If the power sunroof switch and the hard wired circuitry test okay, but the motor or the express or Excess Force Limitation (EFL) features are still ineffective following the calibration and initialization procedures, the motor and module must be replaced as a unit.

REMOVAL

REMOVAL

WARNING: Do not attempt to move or reposition the sunroof glass panel or drive cables with the sunroof motor and module unit removed. Damage to the vehicle, to the sunroof or personal injuries may result.

WARNING: The Sunroof Motor And Module Initialization procedure must be completed any time a sunroof motor and module unit is replaced with a new component. Failure to perform this procedure may result in damage to the vehicle, to the sunroof or in serious or fatal injuries.

1. Disconnect and isolate the battery negative cable.
2. Lower the back of the headliner (1) to gain access to the module unit (4). Refer to **HEADLINER, REMOVAL** .
3. Remove the three screws (2) that secure the motor and module to the sunroof frame.
4. Lower the motor and module unit far enough to access and disconnect the sunroof wire harness connector from the motor and module connector receptacle (3).
5. Remove the sunroof motor and module unit from the vehicle.

INSTALLATION

INSTALLATION

WARNING: Do not attempt to move or reposition the sunroof glass panel or drive cables with the sunroof motor and module unit removed. Damage to the vehicle, to the sunroof or personal injuries may result.

WARNING: The Sunroof Motor And Module Initialization procedure must be completed any time a sunroof motor and module unit is replaced with a new component. Failure to perform this procedure may result in damage to the vehicle, to the sunroof or in serious or fatal injuries.

1. Position the sunroof motor and module unit (4) close enough to connect the wire harness connector to the motor and module connector receptacle (3).
2. Position the motor and module onto the sunroof frame.
3. Install and tighten the three screws (2) that secure the motor and module to the sunroof frame.
4. Install the rear of the headliner. Refer to **HEADLINER, INSTALLATION** .
5. Reconnect the battery negative cable.
6. Perform the Sunroof Position Calibration procedure followed by the Excessive Force Limitation (EFL) Calibration procedure. Refer to **MODULE, POWER SUNROOF, MODULE PROGRAMMING**.

MODULE PROGRAMMING

EXCESSIVE FORCE LIMITATION (EFL) CALIBRATION

NOTE: Verify the battery is in good condition prior to performing this procedure. Do not leave the vehicle on a battery charger while performing this procedure. If the voltage at the sunroof motor/module drops below 11 volts or exceeds 15 volts at anytime while this procedure is being performed, the Excessive Force Limitation (EFL) function will not be properly calibrated.

1. Depress the VENT push button of the sunroof switch so that the sliding glass panel travels to the fully vented position.

2. Depress the CLOSE push button of the sunroof switch so that the sliding glass panel travels to the fully closed position.
3. Depress the OPEN push button of the sunroof switch so that the sliding glass panel travels to the fully open position.
4. Depress the CLOSE push button of the sunroof switch so that the sliding glass panel travels to the fully closed position.
5. Repeat steps 2 through 5 for at least 5 complete sliding glass panel cycles (VENT, CLOSE, OPEN, CLOSE).

EXCESSIVE FORCE LIMITATION (EFL) OVERRIDE

There are two methods for overriding the obstacle detection feature if the single pane sunroof sliding glass is unable to close due to a known blockage conditions (ice, leaves, debris in the track).

- **OVERRIDE - METHOD 1** - Depress and hold the CLOSE push button of the sunroof switch during the close. The sunroof will be in override mode during the close.
- **OVERRIDE - METHOD 2** - Once the sunroof encounters and reverse on an obstacle during (one touch) closing three consecutive times, the sunroof will be in override mode. All push button commands will be in manual mode (no one-touch or express mode) while the obstacle detection feature is in override mode.

EXITING OVERRIDE MODE - Any sunroof obstacle detection override mode is exited by reaching the close position. Once the override has been existed, all normal operation will resume including the obstacle detection feature.

SUNROOF POSITION CALIBRATION

Press the power sunroof switch (Open, Closed, and Vent). If no movement occurs when either the open switch or closed switch is pressed, but the system does move when the vent button is pressed and held, the system is not calibrated. Perform the following procedure to position calibrate the power sunroof system.

1. Turn the ignition to the RUN position.
2. Press the vent button on the power sunroof switch and hold until the sunroof glass panel has moved to the full vent position and the motor movement has stopped for at least 1 second.
3. Press the close switch on the power sunroof switch and hold for a moment (at least 100ms) and release. The sunroof glass panel should continue travel to the full close position. If the sunroof glass panel does not return to the full close position, refer to the appropriate Diagnostic & Testing article for full system diagnosis.
4. Verify proper system operation.

SUNROOF OVERRIDE POSITION CALIBRATION

The sliding glass panel motor stalls when the glass reaches the fully vented position and the electronic motor module learns that position (hard stop), then counts the number of motor rotation to know where the fully closed and fully open positions of the glass are located. The following procedure causes a previously calibrated and properly operating electronic motor module to relearn the fully vented motor stall position. This routine should be performed after the sunroof position calibration procedure has been performed.

1. Be certain the electrical system voltage is at or above 12.5 volts.
2. Be certain that ignition switch is in the ON position.

3. Be certain the power sunshade is open at least beyond the back of the sliding glass panel opening.
4. Depress and hold the VENT push button of the sunroof switch until the sliding glass panel is in the fully vented position or until the motor will not drive the glass any further towards the fully vented position.
5. Open the drivers side front door.
6. Turn the ignition to the OFF position.
7. Within 2 seconds, turn the ignition back to the ON position.
8. Within 2 seconds, depress and hold the vent push button on the sunroof switch for about ten seconds. At the end of ten seconds, the motor will try to drive the sliding glass panel to the fully vented position. Once the motor stall is detected the electronic module will write that stall position to memory as the new glass position.
9. Verify sliding glass panel motor operation by cycling the glass to fully opened, fully closed, fully vented, then fully closed again.

MODULE, RADIO FREQUENCY (RF HUB)

DESCRIPTION

DESCRIPTION

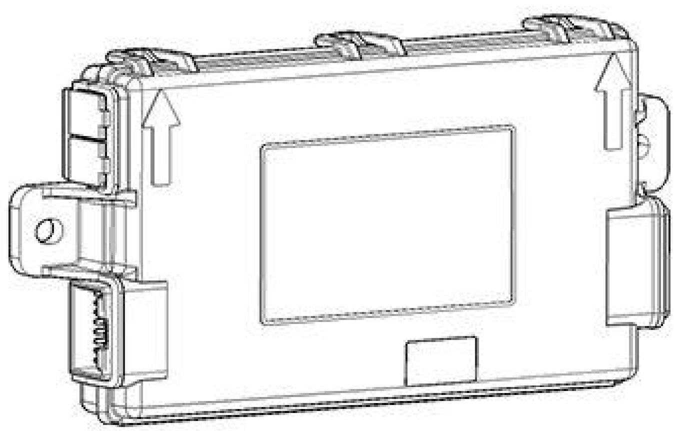

Fig. 70: Radio Frequency Hub Module
Courtesy of CHRYSLER GROUP, LLC

The Radio Frequency Hub Module (RFHM) (2) (also known as the RF Hub/RFH) is a primary component of several standard and optional electronic systems in the vehicle. The RFHM is a Radio Frequency (RF) and Low Frequency (LF) receiver, contains controlling logic for a number of systems and communicates with other electronic modules and nodes in the vehicle over the Controller Area Network (CAN) data bus as well as over a private serial bus. Different signal supporting options include automatic transmission, manual transmission, Passive Entry Keyless go system using smart door handles, the Keyless Ignition Node (KIN) switch, and remote start.

Systems and features supported by the RFHM on Chrysler, Dodge, Jeep vehicles include:

- **Ignition System**
- **Passive Entry (PE) Keyless Go (KG) Systems**
- **Remote Keyless Entry (RKE) System**
- **Remote Start System**
- **Sentry Key Immobilizer System (SKIS)**
- **Vehicle Theft Alarm (VTA) System**

Concealed and protected within the molded black plastic RFHM housing is the microcontroller and the other electronic circuitry of the module. The RFHM is located near the center of the shelf support behind the rear seat back and is concealed beneath the package tray interior trim. It is secured through two mounting tabs integral to the module housing to the shelf support by two nuts on weld studs.

This model RFHM has two connector receptacles integral to the RFHM housing are connected to the vehicle electrical system through dedicated take outs and connectors of the body wire harness. A remote start antenna is located adjacent to the RFHM on the shelf support and is connected directly to the RFHM through a third integral connector receptacle.

The RFHM cannot be adjusted or repaired and, if damaged or ineffective, it must be replaced.

OPERATION

OPERATION

The Radio Frequency Hub Module (RFHM) is an integrated receiver (or base station) in the vehicle that communicates with other electronic modules in the vehicle over either the Controller Area Network (CAN) data bus or a private serial bus to support the following standard and optional vehicle features or systems.

- **Keyless Go Ignition Systems** - The Keyless Ignition Node (KIN) communicates with the FOBIK's through LF signals (125 KHz) then communicates it to RFHM through a private serial bus, then RFHM sends CAN data bus to the Body Control Module (BCM) for IGNITION status after valid key is verified. The RFHM also contains the controlling logic for the back lighting features.
- **Passive Entry** - If the Smart door handles or exterior deck lid release switch are activated, the RFHM signals and monitors the five Low Frequency (LF) antennas. The LF antennas send out Radio Frequency (RF) signals to the FOBIK to verify the FOBIK. When a valid FOBIK is recognized by the RFHM a CAN data bus message is sent to BCM to lock or unlock the vehicle by the RFHM
- **Remote Keyless Entry** - The RFHM receives and monitors RF signals from the Remote Keyless Entry (RKE) transmitter (FOBIK); and relays the appropriate electronic messages BCM module over the CAN data bus to support the features of RKE functions.
- **Remote Start System** - The RFHM receives and monitors RF signals received through the remote start antenna (longer range) from the Remote Keyless Entry (RKE) transmitter or the Passive Entry Keyless Go (PEKG) FOBIK; and relays the appropriate electronic messages to BCM over the CAN data bus to support all RKE functions including optional remote start function.
- **Sentry Key Immobilizer System** - RFHM uses a high security encryption system called "HITAG" for Sentry Key Immobilizer System (SKIM). The system marries FOBIKs, RFHM and ECM with unique secret keys for each vehicle. Swapping parts ARE NOT ALLOWED in the new system. Replacing any part of the system shall be done only in Chrysler authorize dealers using the Chrysler diagnostic scan tool.
- **Vehicle Theft Alarm System** - The RFHM receives and monitors RF signals received from the Remote

Keyless Entry (RKE) transmitter or the Passive Entry Keyless Go (PEKG) FOB with Integrated Key (FOBIK); and relays the appropriate electronic messages to other electronic modules in the vehicle over the CAN data bus to support the features of the optional Vehicle Theft Alarm (VTA) system.

The RFHM is connected to a fused B(+) circuit and has a path to a clean ground at all times. These connections allow it to remain functional regardless of the ignition switch status. Any input to the RFHM that controls a vehicle system function that does not require that the ignition switch status be ON such as depressing a button on an RKE or FOBIK transmitter, prompts the RFHM to wake up and transmit on the CAN data bus.

RFHM uses On-Board Diagnostics (OBD) to monitor all of the Functions and circuits it controls, then sets active and stored Diagnostic Trouble Codes (DTC) for any monitored function faults it detects. RFHM will also send electronic message requests to the Instrument Cluster (IC) through the BCM for the display of certain textual warning messages related to some detected functions conditions or faults.

The hard wired inputs and outputs of the RFHM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. However, conventional diagnostic methods will not prove conclusive in the diagnosis of the RFHM electronic controls or the communication between modules and other devices that provide some features of the RFHM-controlled systems. The most reliable, efficient and accurate means to diagnose the RFHM or the electronic controls and communication related to RFHM-controlled systems operation requires the use of a diagnostic scan tool. Refer to the appropriate Diagnostic & Testing article.

REMOVAL

REMOVAL

1. Disconnect the negative battery cable.
2. Remove the rear shelf cover. Refer to PANEL, REAR SHELF, REMOVAL .

3. Remove the Remote Frequency Hub Module (RFHM) retainers (1).
4. Disconnect the electrical connectors (2).

5. If equipped, disconnect the remote start antenna (3).
6. Remove the RFHM from the vehicle.

INSTALLATION

INSTALLATION

1. Position into place and install the Remote Frequency Hub Module (RFHM) and retainers (1).
2. Connect the electrical connectors (2).
3. If equipped, connect the remote start antenna (3).
4. Install the rear shelf cover. Refer to PANEL, REAR SHELF, INSTALLATION .
5. Connect the negative battery cable.
6. Perform the RFHM programming procedure. This must be completed after a diagnostic repair. Refer to MODULE, RADIO FREQUENCY (RF HUB), MODULE PROGRAMMING.

MODULE PROGRAMMING

RADIO FREQUENCY HUB MODULE (RFHM) PROGRAMMING

NOTE: **If other electronic modules need to be replaced, besides the RFHM, see the "Replacement and Programming Order Guide" before proceeding. Refer to STANDARD PROCEDURE.**

NOTE: **If, during programming, the scan tool instructs to "Enter the vehicle PIN number", care should be taken because the RFHM will only allow 3 consecutive attempts to enter the correct PIN. If 3 consecutive incorrect PIN's are entered, the RFHM will Lock Out the scan tool. To exit Lock Mode, the ignition must remain in the Off position for 25 minutes. All accessories must be off. A battery charger connected to the battery during this time period is recommended.**

NOTE: The Powertrain Control Module (PCM) stores the secret key information. When the RFHM needs to be replaced, the secret key information will be retrieved from the PCM and then transferred to the new RFHM for security use.

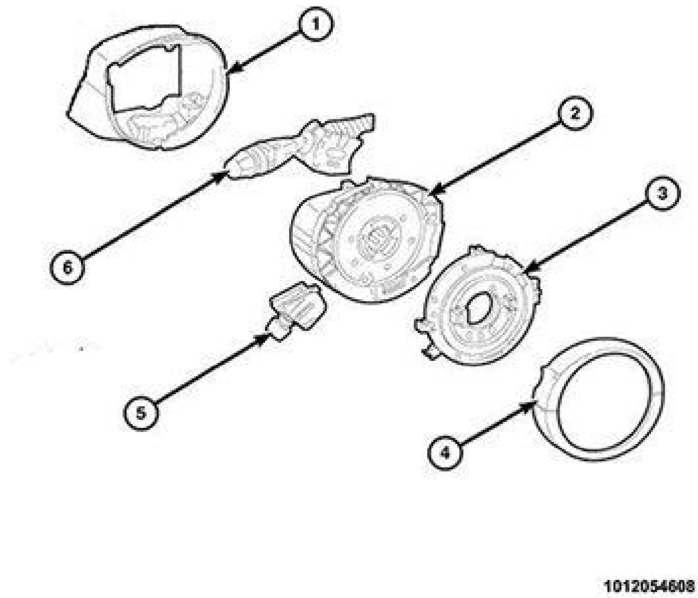
Perform the following after completion of a diagnostic repair:

1. Connect the previously disconnected components and connectors.
2. It may be necessary to obtain the vehicle's unique Personal Identification Number (PIN) assigned to the vehicle. This number can be obtained from the original vehicle invoice or from your Service Manager or Parts Manager.
3. Turn the ignition ON.
4. With the scan tool select: RFH/Radio Frequency Hub.
5. Turn the ignition off.
6. If the RFHM was replaced or any un-programmed or new Frequency Operated Button Integrated Key (FOBIK)s, program all FOBIKs that are to be used with this vehicle. With the scan tool, select "Misc. Functions", "Program Ignition FOBIKs" and follow the instructions on the screen. **All FOBIKs that are to be used in this vehicle must remain on the front seat near the console during programming.**
7. If the RFHM module was replaced, with the scan tool select "Misc. Functions", "RF-HUB Replace" and follow the instructions on the screen.
8. Turn the ignition on then off leaving the key in the ON position.
9. With the scan tool, erase all RFHM DTCs.
10. Operate all equipped RFHM (Passive Entry, Remote Start, Ignition Positions etc.).
11. Wait four minutes.
12. With the scan tool, read the RFHM DTCs.
13. If any RFHM DTCs are present, refer to **DIAGNOSIS AND TESTING** and perform the appropriate diagnostic procedure.
14. If no DTCs are present, the repair is complete.

MODULE, STEERING COLUMN CONTROL

DESCRIPTION

DESCRIPTION



[Fig. 73: Exploded View Of Steering Column Control Module](#)
Courtesy of CHRYSLER GROUP, LLC

The Steering Column Control Module (SCCM) is located near the top of the steering column directly below the steering wheel. The SCCM includes the steering column shroud (1), the Steering Angle Sensor (SAS) (2), the clockspring (3), the multifunction switch (6), a steering column power tilt and telescope switch (5) for vehicles so equipped and a trim cover (4).

The SCCM is secured to the steering column by a unique mounting system using no external fasteners. The SCCM has two key stone features that snap into slots in the upper column jacket to secure the SCCM. In addition, a mechanical red indicator on the lower surface of the column shroud will be flush with the shroud surface when the SCCM is properly installed, but will stand proud of the shroud surface if the key stones are incompletely or improperly seated in the slots of the column jacket.

There are also unique lugs cast into the outer circumference of the steering wheel hub that must be engaged into slots within the inner circumference of the clockspring rotor hub to unlock and drive both the clockspring and the SAS, and the steering wheel must be tightened to specification to ensure proper clockspring and SAS function.

The SCCM includes an integral connector receptacle that faces toward the instrument panel and is connected to the vehicle electrical system through a single take out and connector of the instrument panel wire harness. The instrument panel wire harness take out has been intentionally provided with additional length to facilitate service removal and installation of the SCCM. However, following SCCM installation, this additional length must be pulled back and secured to the instrument panel structure to prevent the potential for undesirable rattling and buzzing noises while driving.

The SCCM shroud, the SAS, the clockspring, the multifunction switch, the steering column power tilt and telescopic switch, as well as the trim cover cannot be adjusted or repaired. If ineffective or damaged the entire SCCM must be replaced as a unit.

OPERATION

OPERATION

The Steering Column Control Module (SCCM) includes an electronic circuit board with a microcontroller. The

microcontroller is a Local Interface Network (LIN) bus master and a gateway for the Controller Area Network (CAN) data bus. Refer to **COMMUNICATION, DESCRIPTION**. The SCCM microcontroller provides power and ground to the multifunction and power tilt and telescope steering column switches of the SCCM, then utilizes integrated circuitry to monitor hard wired analog and digital return inputs from each of these switches. The circuits for the horn switch, the optional heated steering wheel and the standard equipment Driver AirBag (DAB) are pass-through circuits of the SCCM. The steering wheel-mounted electronics functions monitored by the SCCM include the paddle shifter switches and the cruise switches. The output of the horn switch is hard wired to the Body Control Module (BCM) (also known as the Common Body Controller/CBC).

The switch pods in the left and right horizontal spokes of the steering wheel are each LIN bus slave nodes. The switch states of the hands-free communication switches and the Electronic Vehicle Information Center (EVIC) control switches in the left switch pod are communicated over the LIN bus directly to the LIN bus master node of the BCM. The left switch pod also controls the back lighting of both switch pods and both paddle shifter switches. The switch states of the speed control switches in the right switch pod are communicated over the LIN bus to the LIN master node of the SCCM. The internal circuitry of the SCCM gateway then relays electronic message outputs communicating those switch states as well as Steering Angle Sensor (SAS) data to other electronic modules in the vehicle over the CAN bus.

A fixed connector receptacle of the SCCM connects to the vehicle electrical system through a single take out with connector from the instrument panel wire harness. The instrument panel wire harness take out has been intentionally provided with additional length to facilitate service removal and installation of the SCCM. However, following SCCM installation, this additional length must be pulled back and secured to the instrument panel structure to prevent the potential for undesirable rattling or buzzing noises while driving.

The SCCM is connected to a fused B(+) circuit and receives a path to ground at all times. These connections allow it to remain functional regardless of the ignition switch status. Any input to the SCCM that controls a vehicle system function that does not require that the ignition switch status be On such as depressing the horn switch, prompts the SCCM to wake up and transmit on the CAN data bus.

The service replacement SCCM is shipped with the clockspring pre-centered within the SCCM and with a plastic locking tab installed. This locking tab should not be removed until the SCCM has been properly installed on the steering column. If the locking tab is removed before the steering wheel is installed on a steering column, clockspring centering must be confirmed by viewing the inspection window on the clockspring rotor. If the black boxes of the clockspring tape are not visible in the inspection window, the entire SCCM must be replaced with a new unit. Refer to **CLOCKSPRING, STANDARD PROCEDURE** . Proper clockspring installation may also be confirmed by viewing the Steering Angle Sensor (SAS) data using a diagnostic scan tool.

The hard wired circuits between components related to the SCCM may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate SYSTEM WIRING DIAGRAMS article. The wiring information includes wiring diagrams, proper wire and connector repair procedures, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the SCCM or the electronic controls and communication between modules and other devices that provide some features of the SCCM. The most reliable, efficient and accurate means to diagnose the SCCM or the electronic controls and communication related to SCCM operation requires the use of a diagnostic scan tool. Refer to the appropriate Diagnostic & Testing article.

REMOVAL

REMOVAL

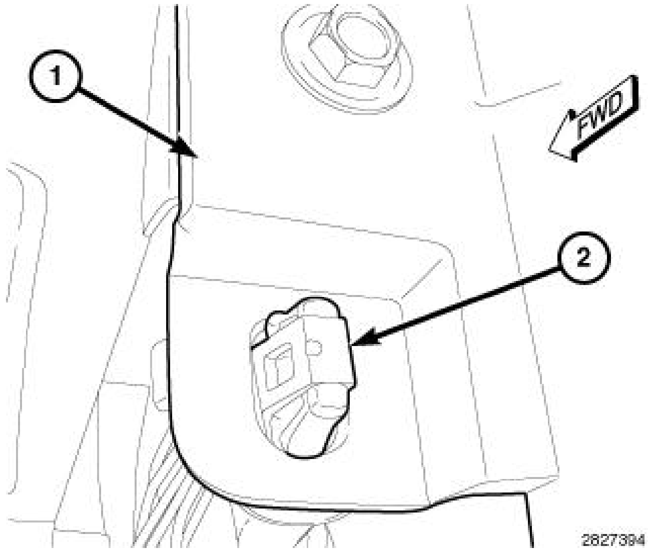


Fig. 74: Retainer Clip & Instrument Panel Base Trim

WARNING: To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.

CAUTION: Always turn the steering wheel until the front wheels are in the straight-ahead position. Then, prior to disconnecting the steering column from the steering gear, lock the steering wheel to the steering column. If clockspring centering has been compromised for ANY reason, the entire Steering Column Control Module (SCCM) and clockspring unit MUST be replaced with a new unit.

1. Place the front wheels in the straight ahead position.
2. Disconnect and isolate the negative cable from the battery. If equipped with an Intelligent Battery Sensor (IBS), disconnect the IBS connector before disconnecting the negative cable from the battery.
3. Remove the Driver AirBag (DAB) from the steering wheel. Refer to **AIR BAG, DRIVER, REMOVAL** .
4. Disconnect the steering wheel wire harness connectors from the upper Steering Column Control Module (SCCM) connector receptacles.
5. Remove the steering wheel from the upper steering column shaft. Refer to **WHEEL, STEERING, REMOVAL** .
6. Using a trim stick or another suitable wide flat-bladed tool, disengage the snap clips that secure the molded hard plastic outer edges of the steering column gap hider bezel to the instrument panel.
7. Pull the gap hider bezel up and away from the instrument panel far enough to access and disengage the retainer clip (2) of the service length of the instrument panel wire harness SCCM take out that secures it to the instrument panel base trim (1) on the right side of the steering column opening.

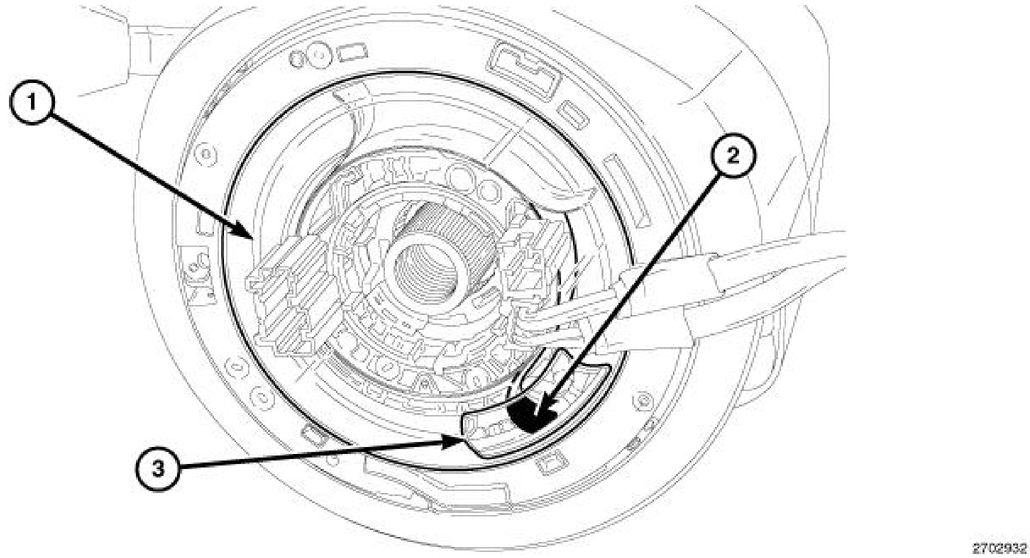
8. Firmly grasp each side of the SCCM shroud (2) on the edges nearest the instrument panel. Use a short, firm tug rearward on the shroud to disengage the spring-loaded upper and lower keystones (6) from the slots (4) in the top and bottom of the steering column jacket (3).
9. Pull the SCCM away from the top of the steering column far enough to reach through the back of the gap hider and shroud to access and disconnect the instrument panel wire harness connector from the lower SCCM connector receptacle.
10. Remove the SCCM from the vehicle.

INSTALLATION

INSTALLATION

WARNING: **To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS) before attempting any steering wheel, steering column, airbag, seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to take the proper precautions could result in accidental airbag deployment.**

CAUTION: **Always turn the steering wheel until the front wheels are in the straight-ahead position. Then, prior to disconnecting the steering column from the steering gear, lock the steering wheel to the steering column. If clockspring centering has been compromised for ANY reason, the entire Steering Column Control Module (SCCM) and clockspring unit MUST be replaced with a new unit.**



[Fig. 76: Inspection Window, Clockspring Rotor & Black Squares](#)
Courtesy of CHRYSLER GROUP, LLC

1. Before reinstalling a Steering Column Control Module (SCCM) onto a steering column, clockspring centering must be confirmed by viewing the inspection window (3) on the clockspring rotor (1). If the black squares (2) on the clockspring tape are not visible through the inspection window, clockspring centering has been compromised and the SCCM **MUST** be replaced with a new unit.
2. Be certain that the front wheels are still in the straight ahead position.
3. If a new SCCM is being installed, disengage the steering column gap hider from the lower edge of the used SCCM shroud and transfer it to the new one.
4. Position the SCCM close enough to the top of the steering column to reach through the back of the gap hider and shroud to reconnect the instrument panel wire harness connector SCCM take out to the lower SCCM connector receptacle.

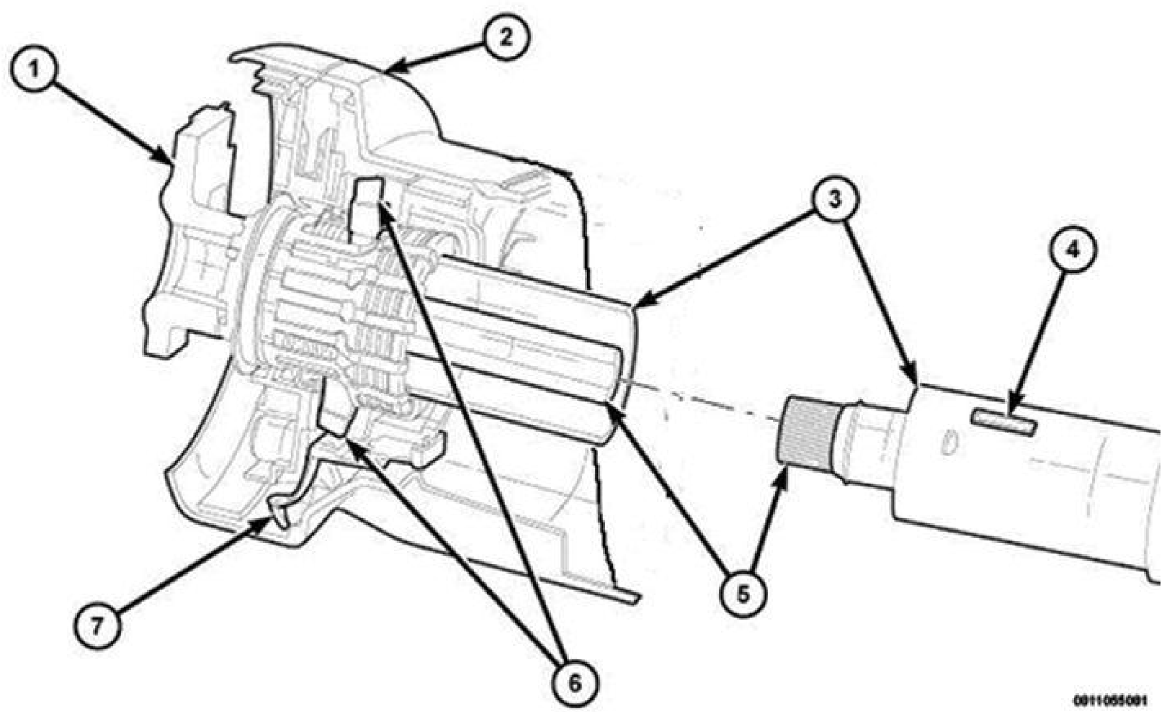


Fig. 77: Steering Column Control Module Shroud, Keystones, Slots & Jacket
Courtesy of CHRYSLER GROUP, LLC

5. Align the hub of the SCCM with the upper steering column shaft (5) and jacket (3).
6. Slide the SCCM over the top of the steering column jacket far enough for the spring-loaded upper and lower keystones (6) to engage the slots (4) in the top and bottom of the steering column jacket.
7. Confirm that the keystones are fully engaged in the column jacket slots by inspecting the round red indicator (7) visible on the lower surface of the SCCM shroud. The indicator should be flush with the shroud. If the indicator stands proud of the shroud, the keystones are **NOT** fully engaged. Carefully slide the SCCM slightly up and down, or rotate it slightly right and left as necessary for the keystones to snap into their slots and the indicator to become flush with the shroud.

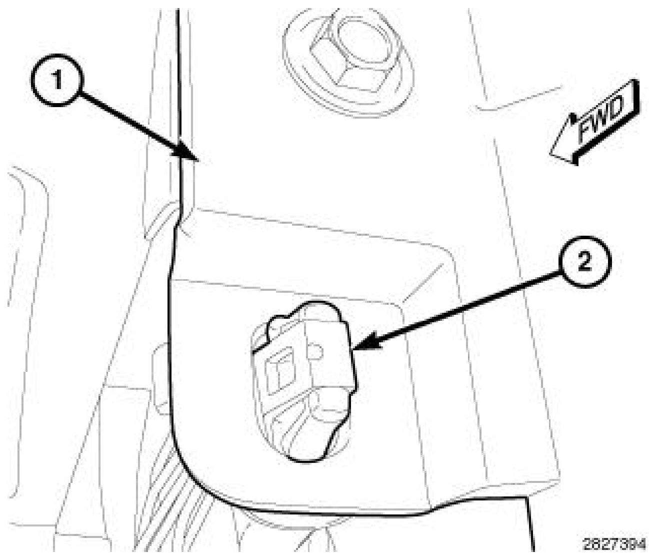

Fig. 78: Retainer Clip & Instrument Panel Base Trim
Courtesy of CHRYSLER GROUP, LLC

NOTE: **The service length of the instrument panel wire harness take out for the SCCM MUST be pulled back out of the SCCM shroud and secured to the instrument panel base trim. Failure to properly accomplish this task will result in unsatisfactory buzzes, squeaks or rattles during vehicle operation.**

8. Pull the gap hider bezel up and away from the instrument panel far enough to access and engage the retainer clip (2) of the service length of the instrument panel wire harness SCCM take out to the instrument panel base trim (1) on the right side of the steering column opening.
9. Align and engage the snap clips that secure the molded hard plastic steering column gap hider bezel to the instrument panel.
10. If a new SCCM is being installed, remove (break off) the red locking tab that secures the clockspring rotor to the clockspring case.
11. Reinstall the steering wheel onto the upper steering column shaft. Be certain to align and insert the rotational lugs on the steering wheel hub into the slots in the hub of the clockspring. Also, the steering wheel fastener **MUST** be tightened to the proper torque specification to ensure proper clockspring and Steering Angle Sensor (SAS) operation. Refer to **WHEEL, STEERING, INSTALLATION** .
12. Reconnect the steering wheel wire harness connectors to the upper SCCM connector receptacles.

13. Reinstall the Driver AirBag (DAB) onto the steering wheel. Refer to **AIR BAG, DRIVER, INSTALLATION** .
14. Reconnect the negative cable to the battery. If equipped with an Intelligent Battery Sensor (IBS), reconnect the IBS connector.

MODULE, TIRE PRESSURE MONITORING (TPM)

DESCRIPTION

DESCRIPTION

The Tire Pressure Monitor (TPM) module is a stand-alone receiver used to perform all TPM functionality in a Premium TPM System on this vehicle. The TPM module is located in the right rear wheel well behind the splash shield and is mounted to the wheel house inner flange with a bracket. The TPM module uses information transmitted from each of the sensors as well as the difference in the strength of the signal received to determine the location of each of the sensors. The TPM module then transmits the required information directly to the Instrument Panel Cluster (IPC) in order to update the lamp, chime and display as required.

OPERATION

OPERATION

The TPM module receives information from each of the sensors in the form of RF signals. The information contained in each of the transmissions provides all the information necessary for the TPM module to determine the pressure in each tire as well as the position of the sensor. This auto locating process only happens in the first 10 minutes of any drive cycle while traveling at speeds above 24 mph (15 km/h) (The auto locating process will start again only if the vehicle has been shut off for approximately 20 minutes or longer).

REMOVAL

REMOVAL

1. Remove the RH splash shield. Refer to **SHIELD, SPLASH, REAR WHEELHOUSE, REMOVAL** .

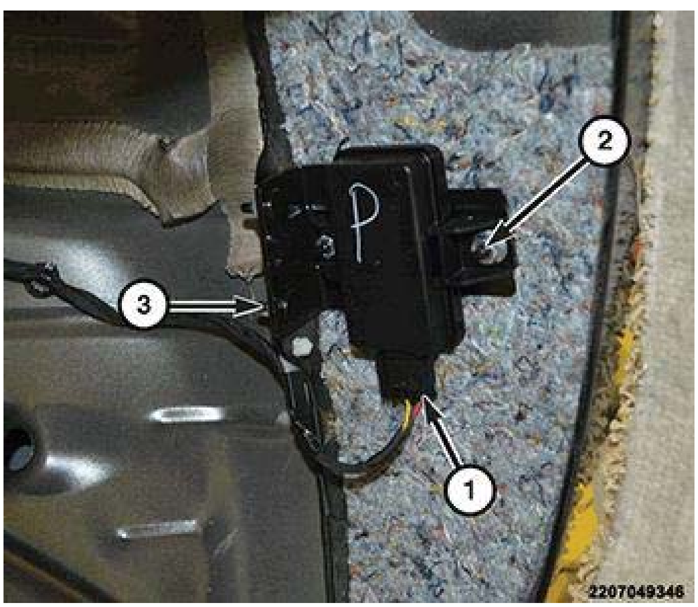

Fig. 79: Tire Pressure Monitoring Module Electrical Connector & Nuts

2. Disconnect the Tire Pressure Monitoring (TPM) Module electrical connector (1).
3. Remove the front TPM module nuts (2), then remove the TPM module nuts (3) from the body flange (3).
4. Remove the TPM module from the vehicle.

INSTALLATION

INSTALLATION

1. Position the Tire Pressure Monitoring (TPM) module in the RH wheel well.
2. Install the front TPM module nuts (2), then install the TPM module nuts (3) at the body flange.
3. Connect the TPM module electrical connector (1).
4. Install RH rear splash shield. Refer to **SHIELD, SPLASH, REAR WHEELHOUSE, INSTALLATION** .
5. Carry out one of the following to update the system for the new sensor ID:
   a. Using the TPM-RKE Analyzer 9936 with the Scan Tool, program the TPM Module with the new tire pressure sensor ID. This is part of the TPM Diagnostic Verification Test. Refer to **STANDARD PROCEDURE** .
   b. The vehicle should remain stationary for at least 20 minutes. Drive the vehicle for a minimum of 20 minutes while maintaining a continuous speed above 24 km/h (15 mph). During this time, the system will recognize and add the new sensor ID.

      This is part of the TPM Diagnostic Verification Test. Refer to **STANDARD PROCEDURE** .

MODULE PROGRAMMING

PROGRAMMING PROCEDURE

1. **TIRE PRESSURE MONITORING (TPM) MODULE**

Was the TPM Module replaced during the test procedure?

Yes

- Go To 2

No

- Go To 3

2. **PLACARD PRESSURE VALUES**
    1. Reconnect the previously removed and/or disconnected components and connectors.
    2. With the scan tool, select "Miscellaneous Functions" in the Body Control Module (BCM). Then select the desired procedure and follow the display on the scan tool.
    3. Program the Placard Pressure Values into the Body Control Module (BCM).
    4. Go To "Tire Pressure Module (TPM)", select "Data Display", read "'Tire Placard Pressure - Front" and "'Tire Placard Pressure -Rear" and confirm the values match the Tire Inflation Pressure (Placard) label. Also, go into the Body Control Module (BCM), select Data Display and read "'Tire Placard Pressure - Front" and "'Tire Placard Pressure -Rear" to confirm the values were programmed correctly. If the Placard values are incorrect in the BCM or TPM Module, select the Body Control Module (BCM) then under "Miscellaneous Functions", select "Update Pressure Threshold" and enter the placard pressure value as seen on the Tire Inflation Pressure (Placard) label.
    5. With the scan tool, erase all stored DTCs.
    6. With the scan tool, read TPM Module DTCs.

Are there any DTCs present?

Yes

- Repair not complete, refer to **DIAGNOSIS AND TESTING** perform the appropriate diagnostic procedure.

No

- Go To 3

3. **TPM SENSOR REPLACEMENT**

NOTE: **If a TPM-RKE Tool is not available, let the vehicle sit stationary for more then 20 minutes, and then proceed to step #4 below.**

1. Using an updated TPM-RKE Analyzer Tool, select TPM Functions, then enter the Model Year and the Body Style of the vehicle, and for the Trigger Selection select PARK SENSOR
2. Scan each TPM Sensor at each road wheel, and store each TPM Sensor ID in the correct location. (LEFT FRONT, LEFT REAR, RIGHT FRONT, RIGHT REAR, and SPARE TIRE (if equipped).)
3. Connect the TPM-RKE Analyzer Tool to the scan tool, and then follow the programming steps outlined in the diagnostic scan tool for "Program Tire Pressure Sensor ID w/ TPM Tool" under "MISC" for the TPM.
4. Drive the vehicle for a minimum of 20 minutes while maintaining a continuous speed above 24 km/h

(15 mph).

5. With the scan tool, read TPM DTCs.

Are there any TPM DTCs present?

Yes

- Perform the appropriate diagnostic procedure. Refer to **DIAGNOSIS AND TESTING** .

No

- Repair complete.

MODULE, TRANSMISSION CONTROL

DESCRIPTION

TRANSMISSION CONTROL MODULE 8-SPEED

CAUTION: The Transmission Control Module (TCM), or Transmission Control Module Assembly (TCMA) is extremely sensitive to Electrostatic Discharge (ESD). Always use a ground strap and follow the ESD guidelines in ELECTROSTATIC DISCHARGE (ESD) SENSITIVE DEVICES. Failure to follow these instructions may result in damage to the TCM/TCMA.

The valve body includes the Transmission Control Module (TCM), all solenoids and sensors, and can be referred to as the Transmission Control Module Assembly (TCMA). The TCM is attached to the valve body between the transmission case and the valve body. If any component of the valve body **including the TCM** sensors or solenoids needs to be replaced, the complete TCMA (valve body) must be replaced. For further information of the TCMA, refer to **VALVE BODY, DESCRIPTION** .

CAUTION: The Transmission Control Module (TCM), or Transmission Control Module Assembly (TCMA) is extremely sensitive to Electrostatic Discharge (ESD). Always use a ground strap and follow the ESD guidelines in ELECTROSTATIC DISCHARGE (ESD) SENSITIVE DEVICES. Failure to follow these instructions may result in damage to the TCM/TCMA.

The valve body, which includes the Transmission Control Module (TCM), controls the delivery and pressure of transmission fluid. The TCM is integrated into the valve body. The TCM regulates the amount of hydraulic pressure used to engage the clutches and the Torque Converter Clutch (TCC), in addition to directing hydraulic pressure to engage or release any given clutch for any given required gear. The TCM will actuate the valves via

solenoids based on the position of the shifter, transmission fluid temperature, engine operating conditions, traction conditions and driver demands. During a shift, the TCM will actuate the solenoids to match the gear ranges to the optimal torque range of the engine based on the position of the accelerator pedal, shifter and vehicle speed as determined by the PCM based on input from the Vehicle Speed Sensor (VSS) and ABS module. Due to the complexity of the 8HP45 transmission control system, always refer to the appropriate Diagnostic & Testing article when attempting to diagnose transmission problems.

If the Transmission Control Module Assembly (TCMA) is replaced, it **must** be programmed and a drive learn needs to be performed before returning the vehicle to the customer. Refer to **STANDARD PROCEDURE** for programming and drive learn procedures .

MODULE PROGRAMMING

PROGRAMMING THE TRANSMISSION CONTROL MODULE (TCM)

PROGRAMMING THE TRANSMISSION CONTROL MODULE (TCM)

NOTE: **New Transmission Control Modules (TCMs) are supplied with generic software. When replacing a TCM, it must be programmed with vehicle specific software.**

NOTE: **Failure to properly program the TCM will cause DTC(s) to be set.**

1. The following conditions must be met during the reprogramming procedure:
   - Battery must be maintained between 10 and 16 volts. Connect a battery charger if necessary.
   - Ambient temperature must be between 0Ā°C (32Ā°F) 60Ā°C (140Ā°F).
   - Gear Selector must be in PARK.
2. With the scan tool and Dealer Connect, download the appropriate TCM flash file to the scan tool.
3. Turn the ignition on.
4. Following the menu on the scan tool, program the TCM.
5. Perform the TCM ADAPTATION procedure. Refer to **MODULE, TRANSMISSION CONTROL, MODULE PROGRAMMING**.
6. Perform the TRANSMISSION VERIFICATION TEST. Refer to **STANDARD PROCEDURE** - 8HP45/845RE, **STANDARD PROCEDURE** - 8HP70 or **STANDARD PROCEDURE** - 8HP90 .

TRANSMISSION CONTROL MODULE (TCM) ADAPTATION - 8HP45 / 845RE / 8HP70 / 8HP90

The TCM or Transmission Control Module Assembly (TCMA) controls the fluid pressure and fill time of each clutch pack to give optimal shift quality. As the clutches wear, the TCM or TCMA will adapt and make adjustments to keep the shift quality consistent over the life of the vehicle. The initial clutch filling pressure and fill times are set at the factory. When a transmission assembly or transmission component is replaced, or when the adaptation values are reset, the adaptation values must be relearned. This procedure should also be followed when it is suspected that a vehicle has not been driven in a manner that encourages clutch adaptation learning in highway or city driving conditions.

NOTE: **The scan tool for some 8-Speed Transmissions now has a QUICK LEARN routine. If the QUICK LEARN routine is available on the scan tool for the application you are working on, then the TCM ADAPTATION PROCEDURES below do not need to be performed.**

QUICK LEARN PROCEDURE

NOTE: **2015 model year vehicles equipped with the 845RE (Sales Code DFL) already contain software in the TCM to enable the Quick Learn procedure. However, 2014 model year vehicles with the 845RE require the Transmission Control Module to be updated to the latest software level.**

NOTE: **The scan tool software must be at the newest revision to perform this procedure.**

NOTE: **The QUICK LEARN PROCEDURE requires that the Transmission fluid temperature be at least 55Ā°C (131Ā°F).**

1. Drive the vehicle briefly to ensure all clutches have been engaged at least twice. Keep the engine running throughout the remainder of this procedure.
2. With the scan tool, activate the RESET ADAPTIVE VALUES routine.
3. With the scan tool, activate the QUICK LEARN routine and follow the on-screen instructions. This procedure requires about 2-5 minutes to complete.

TCM ADAPTATION PROCEDURES

The two procedures to relearn these values are called Fast Filling Adaptation and Standard Clutch Filling Adaptation. Depending on the repair or complaint, one or both procedures must be performed as described below.

NOTE: **Performing a reset of the Transmission Adaptation values does not automatically trigger the TCM to relearn the Adaptation values. If a reset is performed, both procedures must be performed to restore optimal shift quality. Do not reset these values unless specifically instructed to do so.**

NOTE: **This procedure does not need to be performed if the existing TCM or TCMA is re-flashed and that was the only repair performed.**

One or both TCM Adaptation procedures should be performed depending on the situation. Failure to perform these procedures when required could cause shift quality issues.

Fast Filling Adaptation Procedure

Perform the following procedure when the TCM or TCMA, or Transmission assembly (with TCMA) has been replaced, or when the adaptation values have been reset. This procedure should be performed before performing the Standard Clutch Filling Adaptation Procedure when these components are replaced.

NOTE: Perform this procedure on a smooth road surface. The TCM or TCMA will abort the adaptation process if it senses rough road conditions. The road should be clear of traffic due to the start, stop, and slow vehicle speeds required during this procedure.

1. With the Scan Tool, erase Diagnostic Trouble Codes (DTCs).
2. Setup the scan tool to display the Transmission Oil Temperature, Torque, Turbine (Input) Speed Sensor RPM, and Clutch 'X' - Filling Counter for each clutch.
3. Drive the vehicle until the Transmission Oil Temperature is above 30Ā° C (86Ā° F).
4. Stop the vehicle.
5. Drive the vehicle to perform upshifts for all gears under the following conditions:
   - Light to medium throttle position
   - Turbine (Input) Speed between 1, 250 - 2, 000 RPM
   - Torque between 100 N.m and 150 N.m (74 ft. lbs. and 111 ft. lbs.)
6. Release the throttle (0% position) to coast and allow a 6-5 down-shift.
7. Perform steps 4-6 until the Filling Counters for each clutch displays 10 counts.

   The tables below may be used as an alternate reference for the optimal conditions required to learn the Fast Filling Adaptations.

FAST FILLING ADAPTATION CONDITIONS TABLE

8. Perform the Standard Clutch Filling Adaptation Procedure.

Standard Clutch Filling Adaptation Procedure

Perform the following procedure when a Transmission internal component, Torque Converter, TCM or TCMA, or Transmission has been replaced, or when the adaptation values have been reset. This procedure should also be performed if it is suspected that the vehicle has not been driven in a manner that encourages clutch adaptation learning in highway or city driving conditions.

NOTE: **Perform this procedure on a smooth road surface. The TCM or TCMA will abort the adaptation process if it senses rough road conditions. The road should be clear of traffic due to the start, stop, and slow vehicle speeds required during the procedure.**

NOTE: **The TCM learns the Standard Clutch Filling Adaptation values when the applicable clutch is not applied.**

1. With the Scan Tool, erase DTCs.
2. Setup the scan tool to display the Transmission Oil Temperature, Torque, Turbine (Input) Speed Sensor RPM, and Clutch 'X' - Fast Filling Counter for each clutch.
3. Drive the vehicle until the Transmission Oil Temperature is above 50Ā° C (122Ā° F).

   NOTE: **Adaptation learning will be aborted if the Transmission Oil Temperature is above 100Ā° C (212Ā° F).**

4. Stop the vehicle.
5. Drive the vehicle using the paddle shifters or Gear +/- buttons on steering wheel in order to hold the transmission in the desired gear.

   NOTE: **First and second gears do not require a Standard Clutch Filling Adaptation procedure.**

   NOTE: **If attempting to resolve a specific shift quality issue, use the Gear vs Clutch Table below to see which clutches require further adaptation. For instance, if a rough 2-1 downshift is noted, note that clutch C and clutch E are applying and releasing. Then use the Clutch vs Shift Table above to note that clutch C and clutch E require the adaptation procedure performed in 4th and 7th gear.**

6. In 3rd gear, drive the vehicle within the following conditions until the Clutch D - Fast Filling Counter increments by one count:
   - Vehicle speed between 32-56 kph (20-35 mph)
   - Turbine (Input) speed between 950 - 1750 RPM

- Torque between 25 N.m - 180 N.m (18 ft. lbs. - 133 ft. lbs.)

7. In fourth gear, drive the vehicle within the following conditions until the Clutch C - Fast Filling Counter increments by one count:
   - Vehicle speed between 32-56 kph (20-35 mph)
   - Turbine (Input) speed between 950 - 1750 RPM
   - Torque between 25 N.m - 120 N.m (18 ft. lbs. - 89ft. lbs.)

NOTE: Fifth gear does not require a Standard Clutch Filling Adaptation procedure.

8. In sixth gear, drive the vehicle within the following conditions until the Clutch A - Fast Filling Counter increments by one count:
   - Vehicle speed between 73-81 kph (45-50 mph)
   - Turbine (Input) speed between 950 - 1750 RPM
   - Torque between 50 N.m - 120 N.m (37 ft. lbs. - 89ft. lbs.)
9. In seventh gear, drive the vehicle within the following conditions until the Clutch B- Filling Counter and Clutch E Fast Filling Counter each increment by one count:
   - Vehicle speed between 73-81 kph (45-50 mph)
   - Turbine (Input) speed between 950-1750 RPM
   - Torque between 50 N.m-120 N.m (37 ft. lbs.-89ft. lbs.)

The **Standard Clutch Filling Adaptation Conditions Table** below may be used as an alternate reference for the optimal conditions required to learn the Standard Clutch Filling Adaptations.

10. Perform steps 4-9 until the Fast Filling Counters for each clutch has incriminated by at least five counts.
11. Evaluate shift performance for all gears. If the shift quality for any gear is insufficient, execute the appropriate driving conditions until shift quality improves. Incrementing the Fast Filling Counters by 12 counts for each clutch may be necessary to properly learn the adaptation values.

The following table Controller Area Network (CAN) be used to determine which clutches are involved in a specific up-shift or down-shift quality issue. 'X' indicates when a clutch is applied. The Standard Clutch Filling Adaptation learning occurs when the applicable clutch is not applied and the transmission is in a steady state (not shifting).

Reading Clutch Adaptation Data

The Clutch Packs will each have 4 scan tool data labels to observe under the TCM section. Using Clutch A as an example, the data labels are:

- **Clutch A- Fast Filling Counter:** This data label displays the number of Clutch Filling Pressure adaptations that have been performed. These adaptations are the first learned values on a new transmission or after clutch adaptation values are reset. You will need to allow 5 to 12 fast filling counts per clutch to properly learn the clutch adaptations. If the shift quality is sufficient after 5 counts, no further adaptation learns for that clutch are necessary.
- **Clutch A- Filling Counter:** This data label displays the number of Clutch Filling Time adaptations that have been performed. You will need to allow 5 to 12 filling counts per clutch to properly learn the clutch adaptations. If the shift quality is sufficient after 5 counts, no further adaptation learns for that clutch are necessary.
- **Clutch A- Filling Pressure:** This data label displays the clutch filling pressure value that is learned during

the TCM Adaptation procedure. The TCM adaptation software will increase or decrease the clutch fluid filling pressure to improve shift performance. The clutch Filling Pressure value will change over the life of the transmission based first on initial transmission build variation and then due to normal clutch wear.

- **Clutch A- Filling Time:** This data label displays the clutch filling time value that is learned during the TCM Adaptation procedure. The TCM adaptation software will increase or decrease the Clutch Filling Time to improve shift performance. The clutch Filling Time value will change over the life of the transmission based first on initial transmission build variation and then due to normal clutch wear.

DIAGNOSIS AND TESTING

C15C1-00-EPS MECHANICAL PERFORMANCE

For a complete wiring diagram, **refer to appropriate SYSTEM WIRING DIAGRAMS article** .

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Ignition on.
- System voltage between 10.0 and 16.0 volts.
- Vehicle speed above 30 km/h (19 mph).

SET CONDITION

- Electric Power Steering (EPS) Module detects high friction in the steering system when requesting a motor torque change and rotor positioning is not responding within two seconds.

DEFAULT ACTION

- EPS is disabled.

POSSIBLE CAUSES

Possible Causes
SUSPENSION DAMAGE OR MECHANICAL FAILURE
STEERING GEAR IMPROPERLY INSTALLED, DAMAGED OR MECHANICAL FAILURE
ELECTRIC POWER STEERING (EPS) MODULE

DIAGNOSTIC TEST

1. **INSPECT THE FRONT SUSPENSION FOR DAMAGE OR MECHANICAL FAILURE**
   1. Turn the ignition off.
   2. Visually inspect the Front Suspension for binding, damage or mechanical failure. Refer to **WHEEL ALIGNMENT, STANDARD PROCEDURE** .

      Were there any problems found?

      Yes

      - Repair as necessary.
      - Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

      No

      - Go To 2
2. **INSPECT THE STEERING GEAR FOR INCORRECT INSTALLATION, DAMAGE OR MECHANICAL FAILURE**

   NOTE: **Pay particular attention to the inner tie rod boots for damage.**

   1. Visually inspect the Steering Gear for Improper installation, damage or mechanical failure. Refer to **GEAR, INSTALLATION** .

      Were there any problems found?

Yes

- Repair as necessary.
- Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

No

- Go To 3

3. **CHECK FOR AN ACTIVE DTC**

NOTE: **This DTC must be active for the results of this test to be valid.**

1. Turn the ignition on.
2. With the scan tool, read DTCs and record on vehicle work order.
3. With the scan tool, erase DTCs.
4. Test drive the vehicle at road speeds above 30 k/mh (19 mph) and evaluate return effort of power steering.
5. Park the vehicle.
6. With the scan tool, read EPS DTCs.

Is there excessive return effort in the power steering or is the DTC active at this time?

Yes

- Replace the Electric Power Steering (EPS) Module in accordance with Service Information. Refer to **GEAR, REMOVAL** .
- Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

No

- The condition or conditions that originally set this DTC are not present at this time. Using the wiring diagrams as a guide, check all related splices and connectors for signs of water intrusion, corrosion, pushed out or bent terminals, and correct pin tension and repair as necessary. If no problems are found, test complete.
- Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

C15DB-00-EPS DISABLED

For a complete wiring diagram, **refer to appropriate SYSTEM WIRING DIAGRAMS article** .

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Ignition on.
- System voltage between 10.0 and 16.0 volts.

SET CONDITION

- DTC C15C1-00 or DTC C2217-00 has set multiple times.

DEFAULT ACTION

- EPS is disabled.
- Power Steering assist is turned off on the next key cycle.

POSSIBLE CAUSES

Possible Causes
ELECTRIC POWER STEERING (EPS) MODULE

DIAGNOSTIC TEST

CHECK FOR AN ACTIVE DTC

NOTE: **If DTC C15C1-00 or C2217-00 are present, refer to the diagnostics for these DTCs before continuing with this diagnostic procedure.**

NOTE: **This DTC must be active for the results of this test to be valid.**

NOTE: **Make sure the ambient temperature of the vehicle is above -40Â°C (-40Â°F)**

1. Turn the ignition on.
2. With the scan tool, read and record the Environmental Data to help identify the conditions in which the DTC was set.
3. With the scan tool, read DTCs and record on vehicle work order.
4. With the scan tool, erase DTCs.
5. Test drive the vehicle at speeds above 30 k/mh (19 mph).
6. Park the vehicle.
7. With the scan tool, read EPS DTCs.

   Is the DTC active?

   Yes

   - Replace the Electric Power Steering (EPS) Module in accordance with service information. Refer to GEAR, REMOVAL .
   - Perform the EPS VERIFICATION TEST. Refer to STANDARD PROCEDURE.

   No

   - The conditions that caused this code to set are not present at this time. Using the wiring diagram/schematic as a guide, inspect the wiring harness and electrical connectors.
   - Perform the EPS VERIFICATION TEST. Refer to STANDARD PROCEDURE.

C2129-16 BATTERY VOLTAGE-CIRCUIT VOLTAGE BELOW THRESHOLD

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Ignition on.
- System voltage between 10.0 and 16.0 volts.

SET CONDITION

- Electric Power Steering (EPS) Module supply voltage below 10.0 volts.

DEFAULT ACTION

- EPS Module supply voltage below 10.0 volts:
    - Power Steering assist reduced.
    - EPS lamp not illuminated.
- EPS Module supply voltage below 9.0 volts:
    - No Power Steering assist.
    - EPS lamp illuminated.

POSSIBLE CAUSES

Possible Causes
CHARGING SYSTEM
(A951) B(+) CIRCUIT OPEN OR HIGH RESISTANCE
(Z906) GROUND CIRCUIT OPEN OR HIGH RESISTANCE
ELECTRIC POWER STEERING (EPS) MODULE

DIAGNOSTIC TEST

1. **CHARGING SYSTEM DTCS PRESENT**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs in the PCM.

    Is there any Charging System or related voltage DTCs present?

    Yes

    - Perform the appropriate diagnostic procedure. Refer to **DTC INDEX** .

    No

    - Go To 2
2. **CHECK FOR AN ACTIVE DTC**

    NOTE: **Make sure the battery is fully charged.**

    1. Turn the ignition on.
    2. With the scan tool, read DTCs and record on vehicle work order.
    3. With the scan tool, erase DTCs.

4. Start the engine.
5. With the scan tool, read the DTCs while turning the steering wheel from stop to stop.

   Is the DTC active?

   Yes

   - Go To 3

   No

   - Test complete, the condition or conditions that originally set this DTC are not present at this time.

3. **(A951) B(+) CIRCUIT OPEN OR HIGH RESISTANCE**
   1. Turn ignition off.
   2. Disconnect the EPS Module C1 harness connector.
   3. Turn the ignition on.

   NOTE: **Wiggle test the wiring harness and electrical connectors while testing the circuit.**

   NOTE: **The test light must illuminate brightly. Compare the brightness to that of a direct connection to the battery.**

   4. With a 12-volt test light connected to ground, check the (A951) Fused B+ circuit at the EPS C1 harness connector.

   Does the test light illuminate brightly?

   Yes

   - Go To 4

   No

   - Repair the (A951) Fused B+ circuit for an open or high resistance.
   - Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

4. **(Z906) GROUND CIRCUIT OPEN OR HIGH RESISTANCE**
   1. Turn ignition off.

   NOTE: **Wiggle test the wiring harness and electrical connectors while testing the circuit.**

   2. With a test light connected to B+ check (Z906) Ground circuit at the EPS Module C1 harness connector.

   Does the test light illuminate brightly?

Yes

- Replace the Electric Power Steering (EPS) Module in accordance with the service information. Refer to **GEAR, REMOVAL** .
- Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

No

- Repair the (Z906) Ground circuit for an open or high resistance.
- Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

C2129-17 BATTERY VOLTAGE-CIRCUIT VOLTAGE ABOVE THRESHOLD

For a complete wiring diagram, **refer to appropriate SYSTEM WIRING DIAGRAMS article** .

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Ignition on.
- System voltage between 10.0 and 16.0 volts.

SET CONDITION

- Electric Power Steering (EPS) Module detects the battery voltage has increased above 16.5 volts for more than 1 second.

DEFAULT ACTION

- EPS is disabled.

POSSIBLE CAUSES

Possible Causes
CHARGING SYSTEM DTCS PRESENT
ELECTRIC POWER STEERING (EPS) MODULE

DIAGNOSTIC TEST

1. **CHARGING SYSTEM DTCS PRESENT**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs in the PCM.

    Are there any Charging System or related voltage DTCs present?

    Yes

    - Perform the appropriate Charging System DTC diagnostic procedures before continuing with this test. Refer to **DTC INDEX** .

    No

- Go To 2

2. **CHECK FOR AN ACTIVE DTC**

NOTE: This DTC must be active for the results of this test to be valid.

1. Turn the ignition on.
2. With the scan tool, read DTCs and record on vehicle work order.
3. With the scan tool, erase DTCs.
4. Start the engine.
5. With the scan tool, read EPS DTCs.

Is the DTC active?

Yes

- Replace the Electric Power Steering (EPS) Module in accordance with the service information. Refer to **GEAR, REMOVAL** .
- Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

No

- Test complete, the condition or conditions that originally set this DTC are not present at this time.
- Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

C212A-84 SYSTEM VOLTAGE-SIGNAL BELOW ALLOWABLE RANGE

For a complete wiring diagram, **refer to appropriate SYSTEM WIRING DIAGRAMS article** .

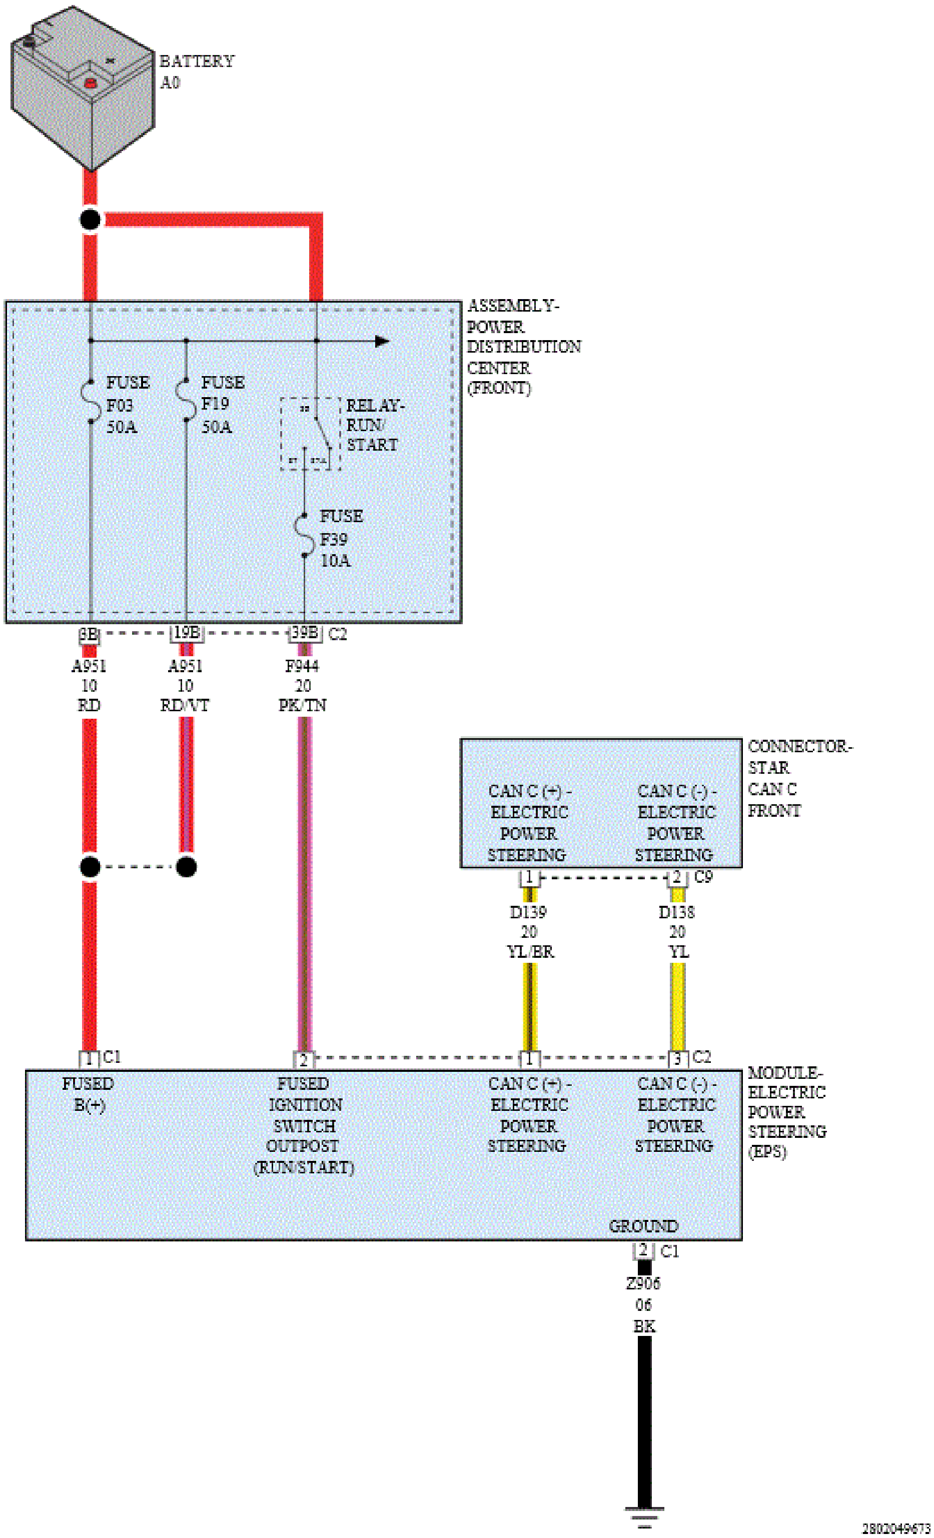

Fig. 2: Electric Power Steering Module Circuit Diagram
Courtesy of CHRYSLER GROUP, LLC

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Ignition on.
- System voltage between 10.0 and 16.0 volts.

SET CONDITION

- Electric Power Steering (EPS) Module receives a message over the CAN bus that battery voltage has decreased below 10.0 volts.

DEFAULT ACTION

- Electric Power Steering (EPS) Module operates correctly and stores the DTC.

POSSIBLE CAUSES

Possible Causes
CHARGING SYSTEM VOLTAGE LOW
ELECTRIC POWER STEERING (EPS) MODULE

DIAGNOSTIC TEST

1. **CHARGING SYSTEM DTCS PRESENT**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs in the PCM.

    Is there any Charging System or related voltage DTCs present?

    Yes

    - Perform the appropriate diagnostic procedure. Refer to **DTC INDEX** .

    No

    - Go To 2
2. **CHECK FOR AN ACTIVE DTC**

    NOTE: **Make sure the battery is fully charged.**

    1. Turn the ignition on.
    2. With the scan tool, read DTCs and record on vehicle work order.
    3. With the scan tool, erase DTCs.
    4. Start the engine.
    5. Turn the steering wheel from stop to stop.
    6. Turn the ignition off.
    7. Turn the ignition on.
    8. With the scan tool, read EPS DTCs.

    Is the DTC active?

Yes

- Replace the Electric Power Steering (EPS) Module in accordance with the service information. Refer to **GEAR, REMOVAL** .
- Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

No

- Test complete, the condition or conditions that originally set this DTC are not present at this time.

C212A-85 SYSTEM VOLTAGE-SIGNAL ABOVE ALLOWABLE RANGE

For a complete wiring diagram, **refer to appropriate SYSTEM WIRING DIAGRAMS article** .

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Ignition on.
- System voltage between 10.0 and 16.0 volts.

SET CONDITION

- Electric Power Steering (EPS) Module receives a message over the CAN bus that battery voltage has increased above 16.0 volts for more than 15 seconds.

DEFAULT ACTION

- Electric Power Steering (EPS) Module operates correctly and stores the DTC.

POSSIBLE CAUSES

Possible Causes
CHARGING SYSTEM DTCS PRESENT
CHARGING SYSTEM VOLTAGE HIGH
ELECTRIC POWER STEERING (EPS) MODULE

DIAGNOSTIC TEST

1. **CHARGING SYSTEM DTCS PRESENT**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs in the PCM.

    Are there any Charging System or related voltage DTCs present?

    Yes

    - Perform the appropriate Charging System DTC diagnostic procedures before continuing with this test. Refer to **DTC INDEX** .

No

- Go To 2

2. **CHECK THE BATTERY**

NOTE: Make sure the Battery is in good condition.

1. Using the AGM Battery Tester (special tool #GR8-1220KIT-CHRY, AGM Battery Tester/Charger Station), test the Battery before continuing.

   Does the Battery pass the load test for this specific application?

   Yes

   - Go To 3

   No

   - Replace the Battery in accordance with the Service Information. Refer to **BATTERY, REMOVAL** .

3. **CHECK FOR AN ACTIVE DTC**

NOTE: This DTC must be active for the results of this test to be valid.

1. Turn the ignition on.
2. With the scan tool, read DTCs and record on vehicle work order.
3. With the scan tool, erase DTCs.
4. Start the engine.
5. With the scan tool, read EPS DTCs.

   Is the DTC active?

   Yes

   - Replace the Electric Power Steering (EPS) Module in accordance with the service information. Refer to **GEAR, REMOVAL** .
   - Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

   No

   - Test complete, the condition or conditions that originally set this DTC are not present at this time.
   - Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

C2206-00-VEHICLE CONFIGURATION MISMATCH

For a complete wiring diagram, **refer to appropriate SYSTEM WIRING DIAGRAMS article** .

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Ignition on.
- No under voltage DTCs.

SET CONDITION

- Vehicle type is not identified or incorrectly identified.

DEFAULT ACTION

- EPS is disabled.

POSSIBLE CAUSES

Possible Causes
ELECTRIC POWER STEERING (EPS) MODULE
BODY CONTROL MODULE (BCM)

DIAGNOSTIC TEST

1. **CHECK FOR POWERTRAIN CONTROL MODULE (PCM) DTCS**
    1. Turn the ignition on.
    2. With the scan tool, read PCM DTCs.

    Are there any Powertrain Control Module (PCM), Vehicle Identification Number (VIN), or Communication DTCs present?

    Yes

    - Perform the appropriate diagnostic procedure. Refer to **DTC INDEX** .

    No

    - Go To 2
2. **ELECTRIC POWER STEERING (EPS) MODULE**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs and record on the repair order.
    3. With the scan tool, read and record the Environmental Data to help identify the conditions in which the DTC was set.
    4. With the scan tool, erase the DTCs.
    5. Cycle the ignition switch from off to on.
    6. With the scan tool, read EPS DTCs.

    Is the DTC active?

    Yes

    - With the scan tool, select BCM under the ECU selection then "Miscellaneous Functions" and

Restore Vehicle Configuration.

No

- Test complete. The condition or conditions that originally set this DTC are not present at this time. Using the wiring diagrams as a guide, check all related splices and connectors for signs of water intrusion, corrosion, pushed out or bent terminals, and correct pin tension.

C2210-00 ECU OVERTEMPERATURE

For a complete wiring diagram, **refer to appropriate SYSTEM WIRING DIAGRAMS article** .

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Ignition on.
- System voltage between 10.0 and 16.0 volts.

SET CONDITION

- Electric Power Steering (EPS) Module is sensing steering system temperature is above 130Ā°C (266Ā°F).

DEFAULT ACTION

- EPS System has lost partial or full assist.

POSSIBLE CAUSES

Possible Causes
STEERING GEAR MECHANICAL FAILURE
ELECTRIC POWER STEERING (EPS) MODULE

DIAGNOSTIC TEST

1. **INSPECT THE STEERING GEAR FOR INCORRECT INSTALLATION, DAMAGE OR MECHANICAL FAILURE**

   NOTE: **Check with customer for unusual driving terrain (e.g. mud, snow, ice) or aggressive driving maneuvers at the time of set condition.**

   Turn the ignition off.

   1. Visually inspect the Steering Gear for Improper installation, damage or mechanical failure. Refer to **GEAR, INSTALLATION** .

      Were any problems found?

      Yes

      - Repair as necessary.

- Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

No

- Go To 2

2. **CHECK FOR AN ACTIVE DTC**

NOTE: **This DTC must be active for the results of this test to be valid.**

NOTE: **Let the vehicle sit for 30 minutes before continuing with this test.**

1. Turn the ignition on.
2. With the scan tool, read DTCs and record on vehicle work order.
3. With the scan tool, erase DTCs.
4. Start the engine.
5. Turn the steering wheel from stop to stop four to five times.
6. With the scan tool, read DTCs.

Is the DTC active?

Yes

- Replace the Electric Power Steering (EPS) Module in accordance with service information. Refer to **GEAR, REMOVAL** .
- Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

No

- The conditions that caused this code to set are not present at this time. Using the wiring diagram/schematic as a guide, inspect the wiring harness and electrical connectors.
- Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

C2217-00-ELECTRIC POWER STEERING MODULE INTERNAL

For a complete wiring diagram, **refer to appropriate SYSTEM WIRING DIAGRAMS article** .

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Ignition on.
- System voltage between 10.0 and 16.0 volts.

SET CONDITION

- Electric Power Steering (EPS) Module detects an internal fault.

DEFAULT ACTION

- EPS System has lost partial or full assist.

POSSIBLE CAUSES

Possible Causes
ELECTRIC POWER STEERING (EPS) MODULE

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE DTC**
    1. Turn the ignition on.
    2. With the scan tool, read and record the Environmental Data to help identify the conditions in which the DTC was set.
    3. With the scan tool, read DTCs and record on vehicle work order.

    NOTE: Do not erase the DTCs at this time.

    Is the DTC active?

    Yes

    - Replace the Electric Power Steering (EPS) Module in accordance with service information. Refer to **GEAR, REMOVAL** .
    - Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

    No

    - Go To 2
2. **VERIFY CUSTOMER COMPLAINT**
    1. Check with customer to verify loss or degradation of power steering assist.

    Was the customer complaint related to a loss or degradation of power steering assist?

    Yes

    - Replace the Electric Power Steering (EPS) Module in accordance with Service Information. Refer to **GEAR, REMOVAL** .
    - Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

    No

    - Go To 3
3. **CHECK FOR AN ACTIVE DTC**

    NOTE: This DTC must be active for the results of this test to be valid.

    1. Turn the ignition on.
    2. With the scan tool, read the EPS DTCs.

3. With the scan tool, erase DTCs.
4. Test drive the vehicle at road speeds above 30 k/mh (19 mph).
5. Park the vehicle.
6. With the scan tool, read EPS DTCs.

   Is the DTC active?

   Yes

   - Replace the Electric Power Steering (EPS) Module in accordance with Service Information. Refer to **GEAR, REMOVAL** .
   - Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

   No

   - The condition or conditions that originally set this DTC are not present at this time. Using the wiring diagrams as a guide, check all related splices and connectors for signs of water intrusion, corrosion, pushed out or bent terminals, and correct pin tension and repair as necessary. If no problems are found, test complete.
   - Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

C2219-00-ECU UNABLE TO CONFIGURE/CONFIGURATION NOT LEARNED

For a complete wiring diagram, **refer to appropriate SYSTEM WIRING DIAGRAMS article** .

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Ignition on.
- System voltage between 10.0 and 16.0 volts.

SET CONDITION

- If any of the learned Vehicle Configuration data from the CAN Bus has changed.

DEFAULT ACTION

- EPS system has reduced power steering assist.

POSSIBLE CAUSES

Possible Causes
ELECTRIC POWER STEERING (EPS) MODULE NOT CONFIGURED
ELECTRIC POWER STEERING (EPS) MODULE

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE DTC**

NOTE: If multiple DTCs are present, inspect the wiring and harness connector at the EPS Assembly.

NOTE: If the Electric Power Steering (EPS) Module was replaced, verify that the correct EPS Assembly was installed on the vehicle.

1. Turn ignition on.
2. With the scan tool, read DTCs and record on vehicle work order.
3. With the scan tool, erase DTCs.
4. With the scan tool, read EPS DTCs.

   Is the DTC active?

   Yes

   - Go To 2

   No

   - Test complete. The condition or conditions that originally set this DTC are not present at this time. Using the wiring diagrams as a guide, check all related splices and connectors for signs of water intrusion, corrosion, pushed out or bent terminals, and correct pin tension.

2. **LOST COMMUNICATION DTCS**
   1. With the scan tool, read DTCs.

   Are there any Lost Communication DTCs present?

   Yes

   - Perform the Stored Lost Communication DTC diagnostic procedure. Refer to **STORED LOST COMMUNICATION DTCS** .

   No

   - Go To 3

3. **BODY CONTROL MODULE (BCM) CONFIGURATION**
   1. Using the scan tool, verify that the BCM has been configured.

   Was the BCM been configured correctly?

   Yes

   - Replace the Electric Power Steering (EPS) Module in accordance with the Service Information. Refer to **GEAR, REMOVAL** .
   - Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

   No

- Replace the BCM in accordance with the Service Information. Refer to **MODULE, BODY CONTROL, REMOVAL** .
- Perform the BODY VERIFICATION TEST. Refer to **STANDARD PROCEDURE** .

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Ignition on.
- System voltage between 10.0 and 16.0 volts.
- One valid CAN message received at least once.
- No U0002-00-CAN C Bus Off Performance DTC present.

SET CONDITION

- Electric Power Steering (EPS) Module detects an incorrect CAN message from the Powertrain Control Module (PCM).

DEFAULT ACTION

- EPS System has reduced or degraded assist under some conditions.

POSSIBLE CAUSES

Possible Causes
ELECTRIC POWER STEERING (EPS) MODULE CAN BUS DTCS
POWERTRAIN CONTROL MODULE (PCM) DTCS
ELECTRIC POWER STEERING (EPS) MODULE
POWERTRAIN CONTROL MODULE (PCM)

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE DTC**

   NOTE: This DTC must be active for the results of this test to be valid.

   1. Turn the ignition on.
   2. With the scan tool, read DTCs and record on vehicle work order.
   3. With the scan tool, erase DTCs.
   4. Cycle the ignition switch from off to on.
   5. With the scan tool, read EPS DTCs.

   Is the DTC active?

   Yes

   - Go To 2

   No

   - Test complete. The condition or conditions that originally set this DTC are not present at this time. Using the wiring diagrams as a guide, check all related splices and connectors for signs of water intrusion, corrosion, pushed out or bent terminals, and correct pin tension.

2. **CHECK FOR POWERTRAIN CONTROL MODULE (PCM) DTCS**
   1. With the scan tool, read PCM DTCs.

   Are there any PCM DTCs present?

   Yes

   - Refer to DIAGNOSIS AND TESTING and perform the appropriate diagnostic procedure.

   No

   - Go To 3

3. **CHECK OTHER MODULES FOR CAN C BUS DTCS**

1. With the scan tool, read the DTCs.

   Are there any CAN C BUS DTCs present?

   Yes

   - Using the schematics as a guide, check the Powertrain Control Module (PCM) pins, terminals, and connectors for corrosion, damage, or terminal push out. Pay particular attention to all power and ground circuits. If no problems are found, replace the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL, REMOVAL** .

   No

   - Using the schematics as a guide, check the Electric Power Steering (EPS) Module pins, terminals, and connectors for corrosion, damage, or terminal push out. Pay particular attention to all power and ground circuits. If no problems are found, replace the Electric Power Steering (EPS) Module in accordance with the Service Information. Refer to **GEAR, REMOVAL** .
   - Perform the EPS Verification Test. Refer to **STANDARD PROCEDURE**.

   Is the DTC active?

   Yes

   - Go To 2

   No

   - Perform the ABS-INTERMITTENT CONDITION TEST. Refer to **STANDARD PROCEDURE** .

2. **CHECK FOR TRANSMISSION CONTROL MODULE (TCM) DTCS**
   1. With the scan tool, read TCM DTCs.

   Are there any TCM DTCs present?

   Yes

   - Refer to **DIAGNOSIS AND TESTING** and perform the appropriate diagnostic procedure.

   No

   - Go To 3

3. **CHECK OTHER MODULES FOR CAN C BUS DTCS**
   1. With the scan tool, read the DTCs.

   Are there any CAN C BUS DTCs present?

   Yes

   - Using the schematics as a guide, check the Transmission Control Module (TCM) pins, terminals, and connectors for corrosion, damage, or terminal push out. Pay particular attention to all power and ground circuits. If no problems are found, replace the Transmission Control Module (TCM) in accordance with the Service Information. Refer to **MODULE, TRANSMISSION CONTROL, REMOVAL** .

   No

- Using the schematics as a guide, check the Electric Power Steering (EPS) Module pins, terminals, and connectors for corrosion, damage, or terminal push out. Pay particular attention to all power and ground circuits. If no problems are found, replace the Electric Power Steering (EPS) Module in accordance with the Service Information. Refer to **GEAR, REMOVAL** .
- Perform the EPS Verification Test. Refer to **STANDARD PROCEDURE**.

U0415-00-IMPAUSIBLE DATA RECEIVED FROM ABS

For a complete wiring diagram, **refer to appropriate SYSTEM WIRING DIAGRAMS article** .

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Ignition on.
- System voltage between 10.0 and 16.0 volts.
- One valid CAN message received at least once.
- No U0002-88-CAN C Bus Off Performance DTC present.

SET CONDITION

- Electric Power Steering (EPS) Module detects an incorrect CAN message from the Anti-lock Brake System (ABS) Module.

DEFAULT ACTION

- EPS System has reduced or degraded assist under some conditions.

POSSIBLE CAUSES

Possible Causes
ELECTRIC POWER STEERING (EPS) MODULE DTCS
ANTI-LOCK BRAKE SYSTEM (ABS) MODULE DTCS
ELECTRIC POWER STEERING (EPS) MODULE
ANTI-LOCK BRAKE SYSTEM (ABS) MODULE

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE DTC**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs and record on vehicle work order.
    3. With the scan tool, erase DTCs.
    4. Cycle the ignition from off to on.
    5. With the scan tool, read EPS DTCs.

    Is the DTC active?

Yes

- Go To 2

No

- Test complete. The condition or conditions that originally set this DTC are not present at this time. Using the wiring diagrams as a guide, check all related splices and connectors for signs of water intrusion, corrosion, pushed out or bent terminals, and correct pin tension.

2. **CHECK FOR ANTI-LOCK BRAKE SYSTEM (ABS) MODULE DTCS**
   1. With the scan tool, read ABS DTCs.

      Is there any ABS DTCs present?

      Yes

      - Perform the appropriate diagnostic procedure. Refer to **DIAGNOSIS AND TESTING** .

      No

      - Go To 3
3. **CHECK OTHER MODULES FOR CAN C BUS DTCS**
   1. With the scan tool, read the DTCs.

      Are there any CAN C BUS DTCs present?

      Yes

      - Using the schematics as a guide, check the Anti-lock Brake System (ABS) Module pins, terminals, and connectors for corrosion, damage, or terminal push out. Pay particular attention to all power and ground circuits. If no problems are found, replace the Anti-lock Brake System (ABS) Module in accordance with the Service Information. Refer to **MODULE, ANTI-LOCK BRAKE SYSTEM, REMOVAL** .

      No

      - Using the schematics as a guide, check the Electric Power Steering (EPS) Module pins, terminals, and connectors for corrosion, damage, or terminal push out. Pay particular attention to all power and ground circuits. If no problems are found, replace the Electric Power Steering (EPS) Module in accordance with the Service Information. Refer to **GEAR, REMOVAL** .
      - Perform the EPS Verification Test. Refer to **STANDARD PROCEDURE**.

   - Test complete. The condition or conditions that originally set this DTC are not present at this time. Using the wiring diagrams as a guide, check all related splices and connectors for signs of water intrusion, corrosion, pushed out or bent terminals, and correct pin tension.

2. **CHECK BODY CONTROL MODULE (BCM) CAN BUS DTCS ARE PRESENT**
   1. With the scan tool, read the BCM DTCs.

Are there any BCM CAN BUS DTCs present?

Yes

- Perform the appropriate diagnostic procedures. Refer to **DIAGNOSIS AND TESTING** .

No

- Go To 3

3. **CHECK OTHER MODULES FOR CAN C BUS DTCS**
    1. With the scan tool, read the DTCs.

    Are there any CAN C BUS DTCs present?

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE DTC**
    1. Turn the ignition on.
    2. With the scan tool, read EPS DTCs and record on the vehicle repair order.
    3. With the scan tool, erase the EPS DTCs.
    4. Cycle the ignition from off to on.
    5. With the scan tool, read the EPS DTCs.

       Did the DTC return?

       Yes

       - Go To 2

       No

       - Go To 5
2. **CHECK FOR BODY CONTROL MODULE (BCM) DTCS**
    1. With the scan tool, read the BCM DTCs.

       Are there any BCM CAN Bus DTCs present?

       Yes

       - Perform the appropriate diagnostic procedure. Refer to **DIAGNOSIS AND TESTING** .

       No

       - Go To 3
3. **CHECK FOR FORWARD FACING CAMERA MODULE (FFCM) DTCS**

1. With the scan tool, read the FFCM DTCs.

   Are there any FFCM DTCs present?

   Yes

   - Perform the appropriate diagnostic procedure.

   No

   - Go To 4

4. **CHECK OTHER MODULES FOR DTCS**
   1. With the scan tool, read DTCs.

      Are there any other modules reporting implausible communication DTCs against the FFCM?

      Yes

      - Replace the Forward Facing Camera Module (FFCM).
      - Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

      No

      - Using the schematics as a guide, check the EPS pins, terminals, and connectors for corrosion, damage, or terminal push out. Pay particular attention to all power and ground circuits. If no problems are found, replace the Electric Power Steering (EPS) Module in accordance with the Service Information. Refer to **GEAR, REMOVAL** .
      - Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

5. **CHECK THE WIRING AND CONNECTORS**
   1. The conditions necessary to set the DTC are not present at this time.
   2. Using the schematics as a guide, inspect the wiring and connectors specific to this module. Wiggle the wiring and connectors while checking for shorted and open circuits.
   3. Check all related splices and connectors for signs of water intrusion, corrosion, pushed out or bent terminals, and correct pin tension.
   4. Check Service Bulletins for any possible causes that may apply.

      Were there any problems found?

      Yes

      - Repair as necessary.
      - Perform the EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

      No

      - Test complete.

U1601-00-ECU APPLICATION SOFTWARE CODE 1 MISSING OR CORRUPTED

For a complete wiring diagram, **refer to appropriate SYSTEM WIRING DIAGRAMS article** .

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Ignition on.
- System voltage between 10.0 and 16.0 volts.

SET CONDITION

- Electric Power Steering (EPS) Module detects that its software has been corrupted or is missing.

DEFAULT ACTION

- EPS is disabled.
- No power steering assist.

POSSIBLE CAUSES

Possible Causes
ELECTRIC POWER STEERING (EPS) MODULE

DIAGNOSTIC TEST

CHECK FOR AN ACTIVE DTC

NOTE: **This DTC must be active for the results of this test to be valid. Check for a loose scan tool connection. Verify battery charger is installed and charge rate provides approximately 13.5 volts.**

1. Turn the ignition on.
2. With the scan tool, read DTCs and record on vehicle work order.
3. With the scan tool, erase DTCs.
4. With the scan tool, read EPS DTCs.

   Is the DTC active?

   Yes

   - Replace the Electric Power Steering (EPS) Module in accordance with the Service Information. Refer to **GEAR, REMOVAL** .
   - Perform EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

   No

   - Test complete. The condition or conditions that originally set this DTC are not present at this time. Using the wiring diagrams as a guide, check all related splices and connectors for signs of water intrusion, corrosion, pushed out or bent terminals, and correct pin tension.
   - Perform EPS VERIFICATION TEST. Refer to **STANDARD PROCEDURE**.

STANDARD PROCEDURE

EPS VERIFICATION TEST

For a complete wiring diagram, **refer to appropriate SYSTEM WIRING DIAGRAMS article** .

EPS VERIFICATION TEST

1. Turn the ignition off.
2. Remove all test equipment.
3. Connect all previously disconnected components and connectors.
4. Verify all accessories are turned off, the battery is fully charged and the charging system has a status of "charged".
5. Verify that the ignition is on. With the scan tool, record and erase all Diagnostic Trouble Codes (DTCs) from all modules. Start the engine and allow it to run for two minutes and fully operate the system that was indicating the failure.

   NOTE: **Turn the steering wheel from stop to stop, holding at each stop position for One second.**

6. Turn the ignition off and wait five minutes. Turn the ignition on and using the scan tool, read DTCs from all modules.
7. If there are no DTCs present after turning ignition on, road test the vehicle for at least five minutes.
8. Again, with the scan tool read DTCs. If any DTCs are present, refer to the **DTC INDEX** in the applicable information for the Diagnostic procedure and troubleshoot the new or recurring symptom.
9. If there are no DTCs present and the customer's concern can no longer be duplicated, the repair is complete.

   Are any DTCs present or is the original concern still present?

   Yes

   - Perform the appropriate diagnostic procedure. Refer to **DIAGNOSIS AND TESTING**.

   No

   - Repair is complete.

2015-16 ENGINE

3.6L - Service Information - Challenger

DESCRIPTION

DESCRIPTION

CAUTION: If the engine has experienced a catastrophic failure, THE INTAKE MANIFOLD MUST BE REPLACED!

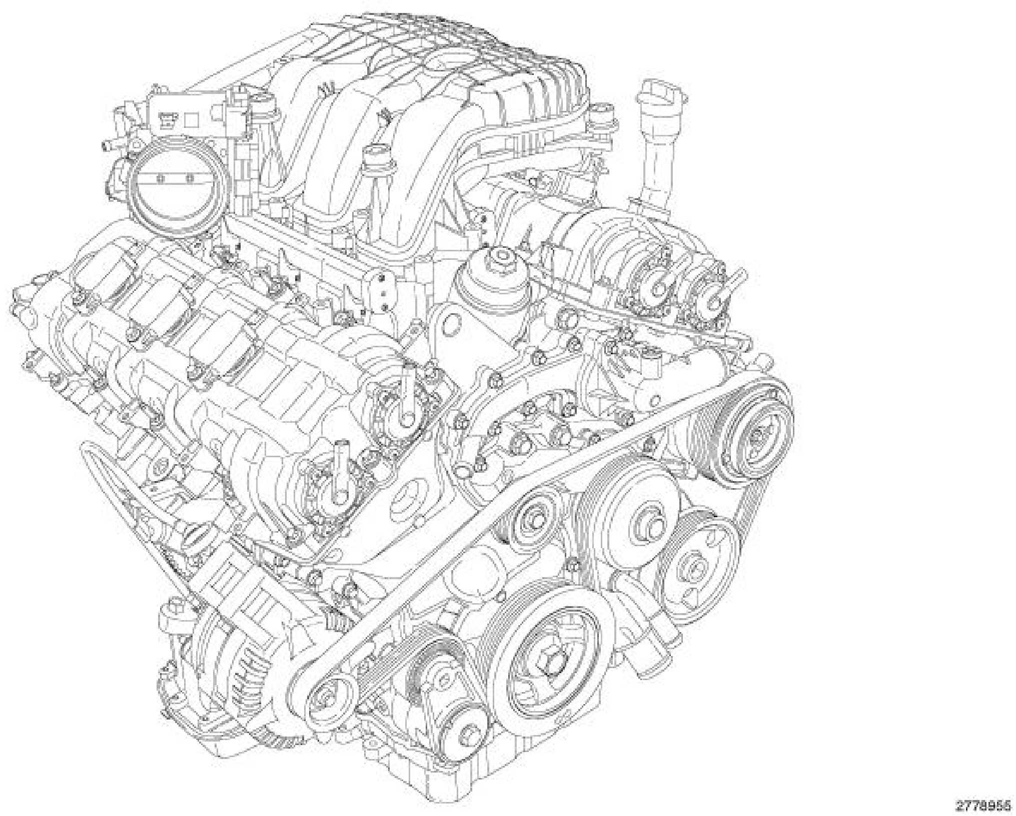

Fig. 1: 3.6L (219.7 CID) Flexible Fuel V-6 Engine
Courtesy of CHRYSLER GROUP, LLC

The 3.6 liter (219.7 CID) flexible fuel V-6 engine features Variable Valve Timing (VVT), Dual Overhead Camshafts (DOHC) and a high-pressure die-cast aluminum cylinder block with steel liners in a 60Â° configuration. The 3.6 liter engine has a chain driven variable discharge oil pump with a two-stage pressure regulator for improved fuel economy. The exhaust manifolds are integrated into the cylinder heads for reduced weight. The cylinders are numbered from front to rear. The right bank is numbered 1, 3, 5 and the left bank is numbered 2, 4, 6. The firing order is 1-2-3-4-5-6. The engine serial number is located on the left side of the cylinder block at the transmission flange.

DIAGNOSIS AND TESTING

ENGINE PERFORMANCE DIAGNOSTIC TABLE

CONDITION	POSSIBLE CAUSE	CORRECTION
ENGINE WILL NOT START	1. Weak battery	1. Charge or replace as necessary. Refer to **BATTERY, DIAGNOSIS AND TESTING** .
	2. Corroded or loose battery connections.	2. Clean and tighten battery connections. Refer to **CLEANING** .
	3. Faulty engine starting system	3. Diagnose engine starting system. Refer to **DIAGNOSIS AND TESTING** .
	4. Faulty coil(s) or control unit	4. Replace ignition coil. Refer to **COIL, IGNITION, REMOVAL** .
	5. Incorrect spark plug gap	5. Set gap. Refer to **SPECIFICATIONS** .
	6. Incorrect cam timing	6. Verify cam timing. Refer to **VALVE TIMING, STANDARD PROCEDURE**.
	7. Contamination in fuel system	7. Clean fuel system and replace fuel filter.
	8. Faulty fuel pump or wiring	8. Repair or replace as necessary.
	9. Faulty Camshaft Position (CMP) sensor	9. Replace the Camshaft Position (CMP) sensor. Refer to **SENSOR, CAMSHAFT POSITION, REMOVAL** .
	10. Faulty Crankshaft Position (CKP) sensor	10. Replace Crankshaft Position (CKP) sensor. Refer to **SENSOR, CRANKSHAFT POSITION, REMOVAL** .
ENGINE STALLS OR ROUGH IDLE	1. Idle speed too low	1. Test minimum air flow. (Refer to Appropriate Diagnostic Information)
	2. Incorrect fuel mixture	2. Refer to Appropriate Diagnostic Information).
	3. Faulty ignition coil(s)	3. Replace ignition coil. Refer to **COIL, IGNITION, REMOVAL** .
	4. Incorrect cam timing	4. Verify cam timing. Refer to **VALVE TIMING, STANDARD PROCEDURE**.
	5. Vacuum leak	5. Inspect intake manifold and vacuum hoses, repair or replace as necessary.
	6. Faulty Crankshaft Position (CKP) sensor	6. (Replace sensor. Refer to **SENSOR, CRANKSHAFT POSITION, REMOVAL** .
ENGINE LOSS OF POWER	1. Dirty or incorrectly gapped spark plugs	1. Correct as necessary. Refer to **SPARK PLUG, REMOVAL** .

CONDITION	POSSIBLE CAUSE	CORRECTION
	2. Contamination in fuel system	2. Clean system and replace fuel filter.
	3. Faulty fuel pump	3. Test and replace the fuel pump. Refer to **MODULE, FUEL PUMP, REMOVAL** .
	4. Incorrect cam timing	4. Verify cam timing. Refer to **VALVE TIMING, STANDARD PROCEDURE**.
	5. Leaking cylinder head gasket	5. Replace cylinder head gasket. Refer to **CYLINDER HEAD, REMOVAL**.
	6. Low compression	6. Determine the cause and repair as necessary. Refer to **CYLINDER COMPRESSION TEST**.
	7. Burned, warped or pitted valves	7. Replace valves as necessary. Refer to **VALVES, INTAKE AND EXHAUST, REMOVAL**.
	8. Plugged or restricted exhaust system	8. Perform exhaust restriction test. Install new parts, as necessary. Refer to **DIAGNOSIS AND TESTING** .
	9. Faulty ignition coil	9. Test and replace ignition coil. Refer to **COIL, IGNITION, REMOVAL** .
ENGINE MISSES ON ACCELERATION	1. Dirty or incorrectly gapped spark plugs	1. Clean spark plugs and set gap. Refer to **SPARK PLUG, REMOVAL** .
	2. Contamination in Fuel System	2. Clean fuel system and replace fuel filter.
	3. Burned, warped or pitted valves	3. Replace valves as necessary. Refer to **VALVES, INTAKE AND EXHAUST, REMOVAL**.
	4. Faulty ignition coil	4. Test and replace ignition coil. Refer to **COIL, IGNITION, REMOVAL** .
ENGINE MISSES AT HIGH SPEED	1. Dirty or incorrectly gapped spark plugs	1. Correct as necessary. Refer to **SPARK PLUG, REMOVAL** .
	2. Faulty ignition coil	2. Test and replace ignition coil. Refer to **COIL, IGNITION, REMOVAL** .
	3. Contamination in fuel system	3. Clean system and replace fuel filter.
	4. Dirty fuel injector(s)	4. Test and replace as necessary (Refer to Appropriate Diagnostic Information).

ENGINE MECHANICAL DIAGNOSTIC TABLE

CONDITION	POSSIBLE CAUSES	CORRECTIONS
NOISY VALVES	1. High or low oil level in crankcase.	1. Refer to **STANDARD PROCEDURE**.
	2. Thin or diluted oil	2. Change oil and filter.
	3. Low oil pressure	3. Check oil pump, if OK, check rod and main bearings for excessive wear.
	4. Dirt in lash adjusters	4. Replace as necessary.
	5. Worn rocker arms	5. Replace as necessary.
	6. Worn lash adjusters	6. Replace as necessary.
	7. Worn valve guides	7. Inspect the valve guides for wear, cracks or looseness. If either condition exists, replace the cylinder head. Refer to **CYLINDER HEAD, REMOVAL**.
	8. Excessive runout of valve seats on valve faces	8. Refer to **STANDARD PROCEDURE**.
CONNECTING ROD NOISE	1. Insufficient oil supply	1. Refer to **STANDARD PROCEDURE**.
	2. Low oil pressure	2. Check oil pump, if OK, check rod and main bearings for excessive wear.
	3. Thin or diluted oil	3. Change oil and filter.
	4. Excessive bearing clearance	4. Replace as necessary.
	5. Connecting rod journal out-of-round	5. Service or replace crankshaft.
	6. Misaligned connecting rods	6. Replace bent connecting rods.
MAIN BEARING NOISE	1. Insufficient oil supply	1. Refer to **STANDARD PROCEDURE**.
	2. Low oil pressure	2. Check oil pump, if OK, check rod and main bearings for excessive wear.
	3. Thin or diluted oil	3. Change oil and filter.
	4. Excessive bearing clearance	4. Replace as necessary.
	5. Excessive end play	5. Check thrust washers for wear.
	6. Crankshaft journal out-of round	6. Service or replace crankshaft.
	7. Loose flywheel or torque converter	7. Tighten to correct torque.

CYLINDER COMPRESSION TEST

NOTE: **The results of a cylinder compression pressure test can be utilized to diagnose**

several engine malfunctions.

NOTE: **Be certain the battery is completely charged and the engine starter motor is in good operating condition. Otherwise the indicated compression pressures may not be valid for diagnosis purposes.**

1. Clean the spark plug recesses with compressed air.
2. Remove the spark plug from the cylinder being tested and record the cylinder number of each spark plug for future reference.
3. Inspect the spark plug electrodes for abnormal firing indicators such as fouled, hot, oily, etc.
4. Disable the fuel system and perform the fuel system pressure release procedure. Refer to FUEL DELIVERY, GAS, STANDARD PROCEDURE .
5. Insert a compression pressure gauge and rotate the engine with the engine starter motor for three revolutions.
6. Record the compression pressure on the third revolution. Continue the test for the remaining cylinders.

   NOTE: **The recommended compression pressures are to be used only as a guide to diagnosing engine problems. An engine should not be disassembled to determine the cause of low compression unless some malfunction is present.**

7. Compression should not be less than 689 kPa (100 psi) and not vary more than 25 percent from cylinder to cylinder.
8. If one or more cylinders have abnormally low compression pressures, repeat the compression test.

   NOTE: **If the same cylinder or cylinders repeat an abnormally low reading on the second compression test, it could indicate the existence of a problem in the cylinder in question.**

9. If one or more cylinders continue to have abnormally low compression pressures, perform the cylinder combustion pressure leakage test. Refer to CYLINDER LEAKAGE TEST.

CYLINDER LEAKAGE TEST

The combustion pressure leakage test provides an accurate means for determining engine condition.

Cylinder leakage testing will detect:

- Exhaust and intake valve leaks (improper seating).
- Leaks between adjacent cylinders or into water jacket.
- Any causes for combustion pressure loss.

1. Check the coolant level and fill as required. DO NOT install the radiator cap.
2. Start and operate the engine until it attains normal operating temperature, then turn the engine OFF.
3. Remove the spark plugs.
4. Remove the oil filler cap.

5. Remove the air cleaner hose.
6. **Calibrate the tester according to the manufacturer's instructions.** The shop air source for testing should maintain a regulated air pressure at 552 kPa (80 psi).
7. Perform the test procedures on each cylinder according to the tester's manufacturer instructions. Set the piston of the cylinder to be tested at TDC on the compression stroke.
8. As each cylinder is pressurized, listen for the air escaping through the throttle body, tailpipe and oil filler cap opening. Check for bubbles in the radiator coolant.

All gauge pressure indications should be equal, with **no more** than 25% leakage.

If leakage is greater then 25%, Refer to CYLINDER LEAKAGE DIAGNOSIS CHART below.

CYLINDER LEAKAGE DIAGNOSIS CHART

CONDITION	POSSIBLE CAUSE	CORRECTION
AIR ESCAPES THROUGH THROTTLE BODY	Intake valve bent, burnt, or not seated properly	Inspect valve and valve seat. Reface or replace, as necessary. Inspect valve springs. Replace as necessary.
AIR ESCAPES THROUGH TAILPIPE	Exhaust valve bent, burnt, or not seated properly	Inspect valve and valve seat. Reface or replace, as necessary. Inspect valve springs. Replace as necessary.
AIR ESCAPES THROUGH RADIATOR	Head gasket leaking or cracked cylinder head or block	Remove cylinder head and inspect. Replace defective part.
MORE THAN 50% LEAKAGE FROM ADJACENT CYLINDERS	Head gasket leaking or crack in cylinder head or block between adjacent cylinders	Remove cylinder head and inspect. Replace gasket, head, or block as necessary.
MORE THAN 25% LEAKAGE AND AIR ESCAPES THROUGH OIL FILLER CAP OPENING ONLY	Stuck or broken piston rings; cracked piston; worn rings and/or cylinder wall	Inspect for broken rings or piston. Measure ring gap and cylinder diameter, taper and out-of-round. Replace defective part as necessary.

OIL CONSUMPTION TEST AND DIAGNOSIS

The following diagnostic procedures are used to determine the source of excessive internal oil consumption, these procedures and tests apply to vehicles with 50, 000 miles or less.

NOTE: **Engine oil consumption may be greater than normal during engine break-in. Repairs should be delayed until vehicle has been driven at least 7, 500 miles.**

Severe service (high ambient temperature, short trips, heavy loading, trailer towing, taxi, off-road, or law enforcement use) may result in greater oil consumption than normal.

Sustained high speed driving and high engine RPM operation may result in increased oil consumption.

Failure to comply with the recommended oil type and viscosity rating, as outlined in the owner's manual, may impact oil economy as well as fuel economy.

Oil consumption may increase with vehicle age and mileage due to normal engine wear.

NOTE: Because a few drops of external oil leakage per mile can quickly account for the loss of one quart of oil in a few hundred miles, be certain there is no external engine oil leaks present.

- **Oil leakage is not the same as oil consumption and all external leakage must be eliminated before any action can be taken to verify and/or correct oil consumption complaints.**
- **Verify that the engine has the correct oil level dipstick and dipstick tube installed.**
- **Verify that the engine is not being run in an overfilled condition. Check the oil level 15 minutes after a hot shutdown with the vehicle parked on a level surface. In no case should the level be above MAX or the FULL mark on the dipstick.**

OIL CONSUMPTION TEST

1. Check the oil level at least 15 minutes after a hot shutdown.
2. If the oil level is low, top off with the proper viscosity and API service level engine oil. Add one bottle of MOPARĀ® 4-In-1 Leak Detection Dye into the engine oil.
3. Tamper proof the oil pan drain plug, oil filter, dipstick and oil fill cap.
4. Record the vehicle mileage.
5. Instruct the customer to drive the vehicle as usual.
6. Ask the customer to return to the servicing dealer after accumulating 500 miles, Check the oil level at least 15 minutes after a hot shutdown. If the oil level is half way between the "FULL" and "ADD" mark continue with the next step.
7. Using a black light, recheck for any external engine oil leaks, repair as necessary, if no external engine oil leaks are present, continue with oil consumption diagnosis.

OIL CONSUMPTION DIAGNOSIS

1. Check the Positive Crankcase Ventilation (PCV) system. Make sure the system is not restricted and the PCV valve has the correct part number and correct vacuum source (18-20 in. Hg at idle below 3000 ft. above sea level is considered normal).
2. Perform a cylinder compression test and cylinder leakage test using the standard cylinder leakage tester and following manufacturers suggested best practices. Refer to CYLINDER COMPRESSION TEST and CYLINDER LEAKAGE TEST.

   NOTE: Verify the spark plugs are not oil saturated. If the spark plugs are oil saturated and compression is good it can be assumed the valve seals or valve guides are at fault.

3. If one or more cylinders have more than 25% leak down further engine tear down and inspection will be required.

TOP 18 REASONS THAT MAY LEAD TO ENGINE OIL CONSUMPTION

1. **Tapered and Out-of-Round Cylinders**

   The increased piston clearances permit the pistons to rock in the worn cylinders. While tilted momentarily, an abnormally large volume of oil is permitted to enter on one side of the piston. The rings,

also tilted in the cylinder, permit oil to enter on one side. Upon reversal of the piston on each stroke, some of this oil is passed into the combustion chamber.

2. **Distorted Cylinders**

   This may be caused by unequal heat distribution or unequal tightening of cylinder head bolts. This condition presents a surface which the rings may not be able to follow completely. In this case, there may be areas where the rings will not remove all of the excess oil. When combustion takes place, this oil will be burned and cause high oil consumption.

3. **Improper operation of "PCV" system**

   The main purpose of the Positive Crankcase Ventilation (PCV) valve is to recirculate blow-by gases back from the crankcase area through the engine to consume unburned hydrocarbons. The PCV system usually has a one way check valve and a make up air source. The system uses rubber hoses that route crankcase blow by gases to the intake manifold. Vacuum within the engine intake manifold pulls the blow by gases out of the crankcase into the combustion chamber along with the regular intake air and fuel mixture.

   The PCV system can become clogged with sludge and varnish deposits and trap blow by gases in the crankcase. This degrades the oil, promoting additional formation of deposit material. If left uncorrected, the result is plugged oil rings, oil consumption, rapid ring wear due to sludge buildup, ruptured gaskets and seals due to crankcase pressurization.

   If equipped with an engine driven vacuum pump, high oil consumption can be caused by unchecked airflow into the pump. This can be caused by anything that opens the vacuum pump intake port up to the atmosphere such as a faulty vacuum pump, hose fitting, hose and brake booster. If there is not a restriction (normally caused by the pump pulling vacuum on the brake booster), then the vacuum pump will pump a high volume of air. This high volume of air will pressurize the crankcase and cause excessive oil burning and oil flow through the PCV system.

4. **Worn Piston Ring Grooves**

   For piston rings to form a good seal, the sides of the ring grooves must be true and flat - not flared or shouldered. Piston rings in tapered or irregular grooves will not seal properly and, consequently, oil will pass around behind the rings into the combustion chamber.

5. **Worn, Broken or Stuck Piston Rings**

   When piston rings are broken, worn or stuck to such an extent that the correct tension and clearances are not maintained, this will allow oil to be drawn into the combustion chamber on the intake stroke and hot gases of combustion to be blown down the cylinder past the piston on the power stroke. All of these conditions will result in burning and carbon build up of the oil on the cylinders, pistons and rings.

6. **Cracked or Broken Ring Lands**

   Cracked or broken ring lands prevent the rings from seating completely on their sides and cause oil pumping. This condition will lead to serious damage to the cylinders as well as complete destruction of the pistons and rings. Cracked or broken ring lands cannot be corrected by any means other than piston replacement.

7. **Worn Valve Stems and Guides**

   When wear has taken place on valve stems and valve guides, the vacuum in the intake manifold will draw oil and oil vapor between the intake valve stems and guides into the intake manifold and then into the cylinder where it will be burned.

8. **Bent or Misaligned Connecting Rods**

   Bent or misaligned connecting rods will not allow the pistons to ride straight in the cylinders. This will prevent the pistons and rings from forming a proper seal with the cylinder walls and promote oil consumption. In addition, it is possible that a bearing in a bent connect rod will not have uniform clearance on the connecting rod wrist pin. Under these conditions, the bearing will wear rapidly and throw off an excessive amount of oil into the cylinder.

9. **Fuel Dilution**

   If raw fuel is allowed to enter the lubrication system, the oil will become thinner and more volatile and will result in higher oil consumption. The following conditions will lead to higher oil consumption:

   - Excess fuel can enter and mix with the oil via a leaking fuel injector
   - Gasoline contaminated with diesel fuel
   - Restricted air intake
   - Excessive idling

10. **Contaminated Cooling Systems**

    Corrosion, rust, scale, sediment or other formations in the water jacket and radiator will prevent a cooling system from extracting heat efficiently. This is likely to cause cylinder distortion thus leading to higher oil consumption.

11. **Oil Viscosity**

    The use of oil with a viscosity that is too light may result in high oil consumption. Refer to the vehicle owner's manual for the proper oil viscosity to be used under specific driving conditions and/or ambient temperatures.

12. **Dirty Engine Oil**

    Failure to change the oil and filter at proper intervals may cause the oil to be so dirty that it will promote accumulation of sludge and varnish and restrict oil passages in the piston rings and pistons. This will increase oil consumption; dirty oil by nature is also consumed at a higher rate than clean oil.

13. **Crankcase Overfull**

    Due to an error in inserting the oil dip stick so that it does not come to a seat on its shoulder, a low reading may be obtained. Additional oil may be added to make the reading appear normal with the stick in this incorrect position which will actually make the oil level too high. If the oil level is so high that the lower ends of the connecting rods touch the oil in the oil pan excessive quantities of oil will be thrown on the cylinder walls and some of it will work its way up into the combustion chamber.

14. **Excessively High Oil Pressure**

    A faulty oil pressure relief valve may cause the oil pressure to be too high. The result will be that the engine will be flooded with an abnormally large amount of oil in a manner similar to that which occurs with worn bearings. This condition may also cause the oil filter to burst.

15. **Aftermarket Performance Chips and Modification**

    Increasing performance through the use of performance/power enhancement products to a stock or factory engine will increase the chance of excessive oil consumption.

16. **Lugging Engine**

    Lugging is running the engine at a lower RPM in a condition where a higher RPM (more power/torque) should be implemented. Especially susceptible on vehicles equipped with a manual transmission. This driving habit causes more stress loading on the piston and can lead to increases in engine oil consumption.

17. **Turbocharged Engines**

    There is a possibility for PCV "push-over" due to higher crankcase pressure (as compared to naturally aspirated engines) which is normal for turbocharged engines. This condition causes varying amounts of engine oil to enter the intake manifold, charge air cooler and associated plumbing to and from the charge air cooler, also a leaking turbocharger seal will draw oil into the combustion chamber where it will burn (blue smoke from tail pipe may be present) and form carbon deposits which contribute to further oil consumption as they interfere with proper engine function.

18. **Restricted Air Intake**

    Excessive restriction in the air intake system will increase engine vacuum and can increase oil consumption, an extremely dirty air filter would be one example of this situation.

STANDARD PROCEDURE

ENGINE GASKET SURFACE PREPARATION

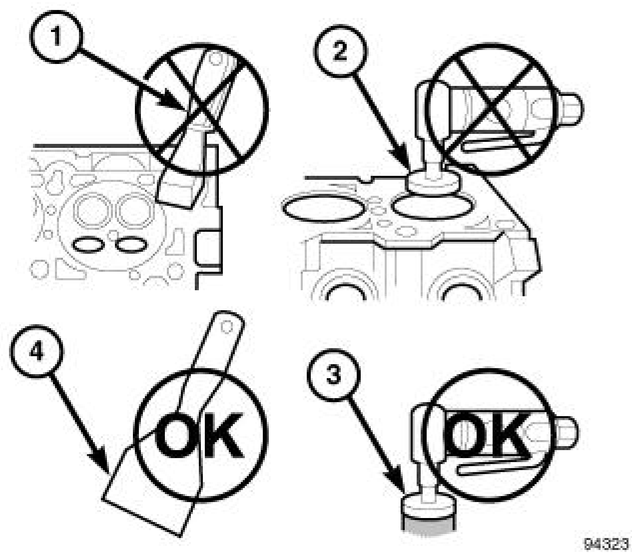

Fig. 2: Proper Tool Usage For Surface Preparation
Courtesy of CHRYSLER GROUP, LLC

To ensure engine gasket sealing, proper surface preparation must be performed, especially with the use of aluminum engine components and multi-layer steel cylinder head gaskets.

Never use the following to clean gasket surfaces:

- Metal scraper (1).
- Abrasive pad or paper to clean cylinder block and head.
- High speed power tool with an abrasive pad or a wire brush (2).

NOTE: **Multi-Layer Steel (MLS) head gaskets require a scratch free sealing surface.**

Only use the following for cleaning gasket surfaces:

- Solvent or a commercially available gasket remover
- Plastic or wood scraper (4).
- Drill motor with 3M Roloc™ Bristle Disc (3), white is used for the aluminum heads and yellow is used for the iron block.

CAUTION: **Excessive pressure or high RPM (beyond the recommended speed), can**

damage the sealing surfaces. The mild (white, 120 grit) bristle disc is recommended. If necessary, the medium (yellow, 80 grit) bristle disc may be used on cast iron surfaces with care.

DUST COVERS AND CAPS

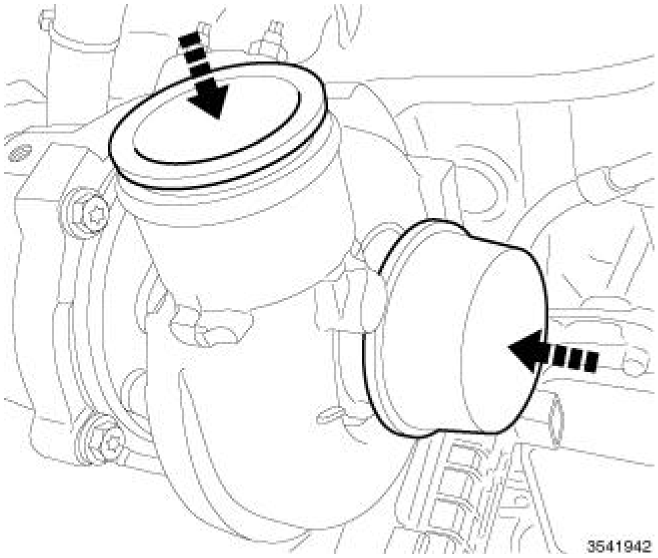

Fig. 3: Covers/Caps
Courtesy of CHRYSLER GROUP, LLC

To avoid the possibility of dust, dirt, moisture and other foreign debris being introduced to the engine during service, cover or cap all openings when hoses and tubes are removed.

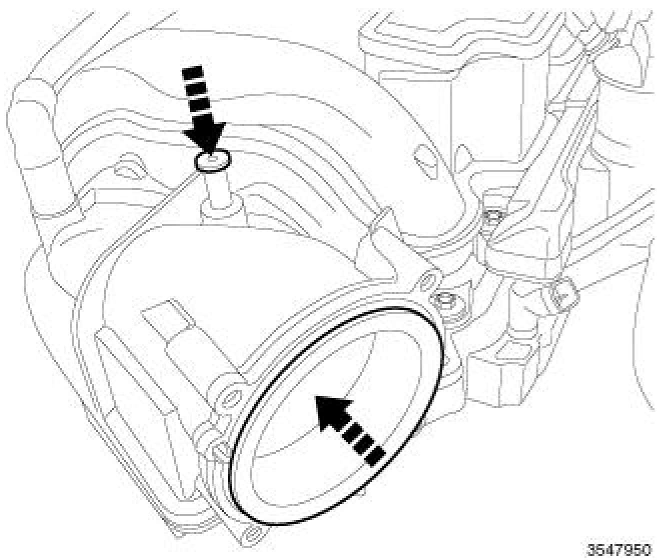

Fig. 4: Opening Cover
Courtesy of CHRYSLER GROUP, LLC

Covers installed over openings will reduce the possibility of foreign materials to entering the engine systems. Using miller tool Universal Protective Cap Set (special tool #10368, Set, Universal Protective Cap), select the appropriate cover needed for the procedure.

REPAIR DAMAGED OR WORN THREADS

CAUTION: Be sure that the tapped holes maintain the original center line.

Damaged or worn threads can be repaired. Essentially, this repair consists of:

- Drilling out worn or damaged threads.
- Tapping the hole with a special Heli-Coil™ Tap, or equivalent.
- Installing an insert into the tapped hole to bring the hole back to its original thread size.

FORM-IN-PLACE GASKETS AND SEALERS

NOTE: All of the sealants mentioned below are not used on every engine, they are listed as a general reference guide. See service information for specific sealer usage.

There are numerous places where form-in-place gaskets are used on the engine. Care must be taken when applying form-in-place gaskets to assure obtaining the desired results.**Do not use form-in-place gasket material unless specified.** Bead size, continuity, and location are of great importance. Too thin a bead can result in leakage while too much can result in spill-over which can break off and obstruct fluid feed lines. A continuous bead of the proper width is essential to obtain a leak-free gasket. All sealing surfaces that use form-in-place gaskets and sealers **must** be free of grease or oil. Surfaces should be cleaned with MoparĀ® brake parts cleaner prior to sealer application. After the sealer is applied, the parts should be assembled within 10 minutes.

There are numerous types of form-in-place gasket materials that are used in the engine area. Each has different properties and can not be used in place of the other.

SEALANT TYPES

- **MOPARĀ® ENGINE SEALANT RTV SILICONE RUBBER ADHESIVE** is used to seal components exposed to engine oil. This material is a specially designed black silicone rubber RTV that retains adhesion and sealing properties when exposed to engine oil. Moisture in the air causes the material to cure. This material is available in three ounce tubes and has a shelf life of one year. After one year this material will not properly cure. Always inspect the package for the expiration date before use.
- **MOPARĀ® ATF-RTV** is a specifically designed black silicone rubber RTV that retains adhesion and sealing properties to seal components exposed to automatic transmission fluid, engine coolants, and moisture. This material is available in three ounce tubes and has a shelf life of one year. After one year this material will not properly cure. Always inspect the package for the expiration date before use.
- **MOPARĀ® GASKET MAKER** is an anaerobic type gasket material. The material cures in the absence of air when squeezed between two metallic surfaces. It will not cure if left in the uncovered tube. The anaerobic material is for use between two machined surfaces. Do not use on flexible metal flanges.
- **MOPARĀ® BED PLATE SEALANT** is a unique (green-in-color) anaerobic type gasket material that is specially made to seal the area between the bed plate and cylinder block without disturbing the bearing clearance or alignment of these components. The material cures slowly in the absence of air when torqued between two metallic surfaces, and will rapidly cure when heat is applied.
- **MOPARĀ® THREEBOND™ ENGINE RTV** is formulated as a high performance temperature

vulcanized silicone with good elasticity, temperature and chemical resistance when cured. It is resistant to engine oil, transmission fluid and gear lube but not recommended for sealing engine coolant.

SEALANT APPLICATION

- MoparÂ® Gasket Maker material should be applied sparingly 1 mm (0.040 in.) diameter or less of sealant to one gasket surface. Be certain the material surrounds each mounting hole. Excess material can easily be wiped off. Components should be torqued in place within 15 minutes. The use of a locating dowel is recommended during assembly to prevent smearing material off the location.
- MoparÂ® Engine Sealant RTV or ATF-RTV gasket material should be applied in a continuous bead approximately 3 mm (0.120 in.) in diameter. All mounting holes must be circled. For corner sealing and "T" joint locations, a 3.17 or 6.35 mm (1/8 or 1/4 in.) drop is placed in the center of the gasket contact area. Uncured sealant may be removed with a shop towel. Components should be torqued in place while the sealant is still wet to the touch (within 10 minutes). The usage of a locating dowel is recommended during assembly to prevent smearing material off the location.
- MoparÂ® Threebond™ Engine RTV Sealant gasket material should be applied in a continuous bead approximately 3 mm (0.120 in.) in diameter. The gasket surfaces should be cleaned with isopropyl alcohol wipes in preparation for sealant application. All mounting holes must be circled. For corner sealing and "T" joint locations, a 3.17 or 6.35 mm (1/8 or 1/4 in.) drop is placed in the center of the gasket contact area. Uncured sealant may be removed with a shop towel. Components should be assembled within 20 minutes and torqued in place within 45 minutes. The usage of a locating dowel is recommended during assembly to prevent smearing material off the location.

REMOVAL

REMOVAL

CAUTION: If the original engine has experienced a catastrophic failure or an individual failure with the piston, cylinder bore, engine block, valve or valve seat, the intake manifold MUST be replaced with a new manifold.

1. Remove the hood. Refer to **HOOD, REMOVAL** .
2. Remove the cowl panel cover. Refer to **COVER, COWL PANEL, REMOVAL** .

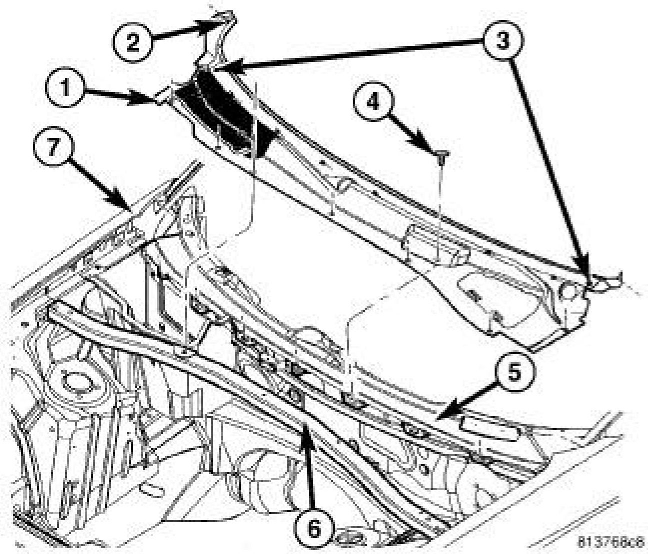

Fig. 5: Removing/Installing Cowl Panel

3. Remove the strut tower support (6).
4. Perform the fuel pressure release procedure. Refer to **FUEL DELIVERY, GAS, STANDARD PROCEDURE** .
5. Disconnect and isolate the negative battery cable.
6. Perform the Refrigerant System Recovery procedure. Refer to **PLUMBING, STANDARD PROCEDURE** .

NOTE: **Left engine mount shown in illustration, right engine mount similar.**

80. Remove the left and right engine mount heat shield nuts (3) and the heat shields (4).
81. Remove the left and right engine mount bolts (2).

CAUTION: **While slowly separating the engine from the vehicle, constant checks must be made to assure proper positioning and that no damage to other components or wiring harnesses occur during separation.**

82. Carefully remove the engine from the engine compartment.
83. If required, remove the following components for installation on the replacement engine:

- Left exhaust down pipe
- Right exhaust down pipe
- Left engine mount bracket
- Left engine mount
- Right engine mount bracket
- Right engine mount
- Accessory drive belt tensioner
- Upper intake manifold support bracket
- Block heater (if equipped).

INSTALLATION

INSTALLATION

CAUTION: If the original engine has experienced a catastrophic failure or an individual failure with the piston, cylinder bore, engine block, valve or valve seat, the intake manifold MUST be replaced with a new manifold.

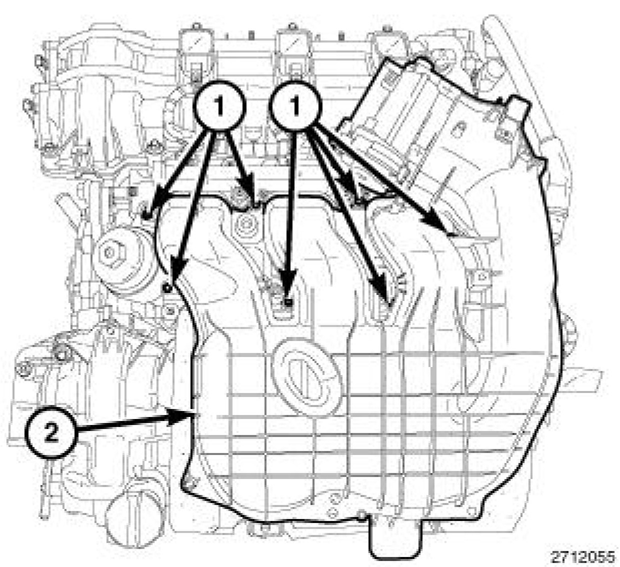

Fig. 45: Upper Intake Manifold & Bolts

NOTE: If installing a replacement engine, transfer components such as engine mount brackets, block heater, accessories, heater hoses and tubes to the replacement engine.

1. If required, transfer the following components onto the replacement engine:
    - Left exhaust down pipe
    - Right exhaust down pipe
    - Left engine mount bracket
    - Left engine mount

- Right engine mount bracket
- Right engine mount
- Accessory drive belt tensioner
- Upper intake manifold support bracket
- Block heater (if equipped)

2. If required, remove the upper intake manifold. Refer to **MANIFOLD, INTAKE, REMOVAL**.

CYLINDER HEAD

DESCRIPTION

DESCRIPTION

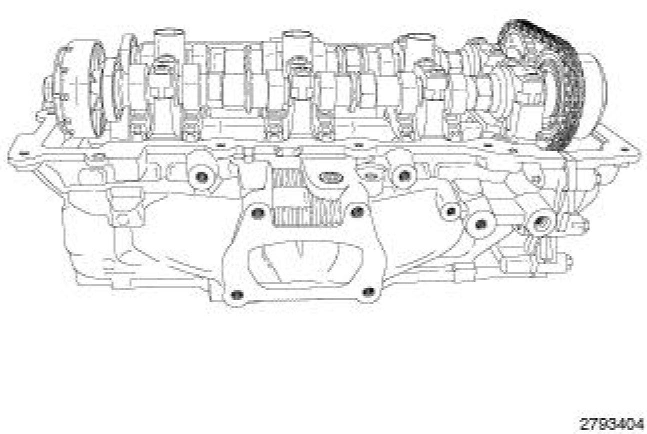

Fig. 97: Aluminum Cylinder Head
Courtesy of CHRYSLER GROUP, LLC

The aluminum cylinder heads are a unique design with left and right castings. The exhaust manifolds are integrated into the cylinder heads. The cylinder head features four valves per cylinder with pressed in powdered metal valve guides. The valve guides are not serviceable. The Dual Over Head Camshaft (DOHC) valvetrain uses roller rocker arms with hydraulic lifters. The cylinder head's camshaft bearing caps are made of powdered metal and the location and direction of each cap is marked on the side of the caps. The spark plug tubes are pressed into the cylinder heads and sealed in place. The tubes are a thin wall design and caution must be taken when working in the spark plug tube area.

DIAGNOSIS AND TESTING

CYLINDER HEAD GASKET

A cylinder head gasket leak can be located between adjacent cylinders or between a cylinder and the adjacent water jacket.

Possible indications of the cylinder head gasket leaking between adjacent cylinders are:

- Loss of engine power
- Engine misfiring
- Poor fuel economy

Possible indications of the cylinder head gasket leaking between a cylinder and an adjacent water jacket are:

- Engine overheating
- Loss of coolant
- Excessive steam (white smoke) emitting from exhaust
- Coolant foaming

CYLINDER-TO-CYLINDER LEAKAGE TEST

To determine if an engine cylinder head gasket is leaking between the cylinders located next to each other, follow the procedures in Cylinder Compression Pressure Test. Refer to CYLINDER COMPRESSION TEST. An engine cylinder head gasket leaking between the cylinders will result in approximately a 50 - 70% reduction in compression pressure.

CYLINDER-TO-WATER JACKET LEAKAGE TEST

WARNING: USE EXTREME CAUTION WHEN THE ENGINE IS OPERATING WITH COOLANT PRESSURE CAP REMOVED.

VISUAL TEST METHOD

With the engine cool, remove the coolant pressure cap. Start the engine and allow it to warm up until thermostat opens.

If a large combustion/compression pressure leak exists, bubbles will be visible in the coolant.

COOLING SYSTEM TESTER METHOD

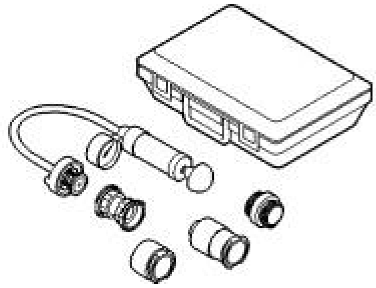

Fig. 98: Cooling System Pressure Tester - 7700a
Courtesy of CHRYSLER GROUP, LLC

WARNING: WITH THE COOLING SYSTEM TESTER IN PLACE, PRESSURE WILL BUILD UP FAST. EXCESSIVE PRESSURE BUILT UP BY CONTINUOUS ENGINE OPERATION MUST BE RELEASED TO A SAFE PRESSURE POINT. NEVER PERMIT THE PRESSURE TO EXCEED 138 kPa (20 psi).

Install Cooling System Tester (special tool #7700-A, Tester, Cooling System) or equivalent to pressure cap neck. Start the engine and observe the tester's pressure gauge. If gauge pulsates with every power stroke of a cylinder a combustion pressure leak is evident.

CHEMICAL TEST METHOD

Fig. 99: Bloc-Chek-Kit - C-3685-A
Courtesy of CHRYSLER GROUP, LLC

Combustion leaks into the cooling system can also be checked by using a (special tool #C-3685-A, Bloc-Chek Kit) or equivalent. Perform the test following the procedures supplied with the tool kit.

HYDRAULIC LASH ADJUSTER

A tappet-like noise may be produced from several items. Check the following items.

1. Engine oil level too high or too low. This may cause aerated oil to enter the adjusters and cause them to be spongy.
2. Insufficient running time after rebuilding the cylinder head. Low speed running up to 1 hour may be required.
3. Turn the engine off and let set for a few minutes before restarting. Repeat this several times after the engine has reached normal operating temperature.
4. Low oil pressure.
5. The oil restricter in cylinder head gasket or the oil passage to the cylinder head is plugged with debris.
6. Air ingested into oil due to broken or cracked oil pump pick up.
7. Worn valve guides.

8. Rocker arm ears contacting valve spring retainer.
9. Rocker arm loose, adjuster stuck or at maximum extension and still leaves lash in the system.
10. Oil leak or excessive cam bore wear in cylinder head.
11. Faulty lash adjuster.
    - Check lash adjusters for "sponginess" while installed in cylinder head and cam on camshaft at base circle. Depress part of rocker arm over adjuster. Normal adjusters should feel firm when pressed quickly. When pressed very slowly, lash adjusters should collapse.
    - Remove suspected lash adjusters, and replace.
    - Before installation, make sure adjusters are full of oil. This can be verified by little plunger travel when lash adjuster is depressed quickly.

REMOVAL

LEFT

CAUTION: **The magnetic timing wheels (1) must not come in contact with magnets (pickup tools, trays, etc.) or any other strong magnetic field. This will destroy the timing wheels ability to correctly relay camshaft position to the camshaft position sensor.**

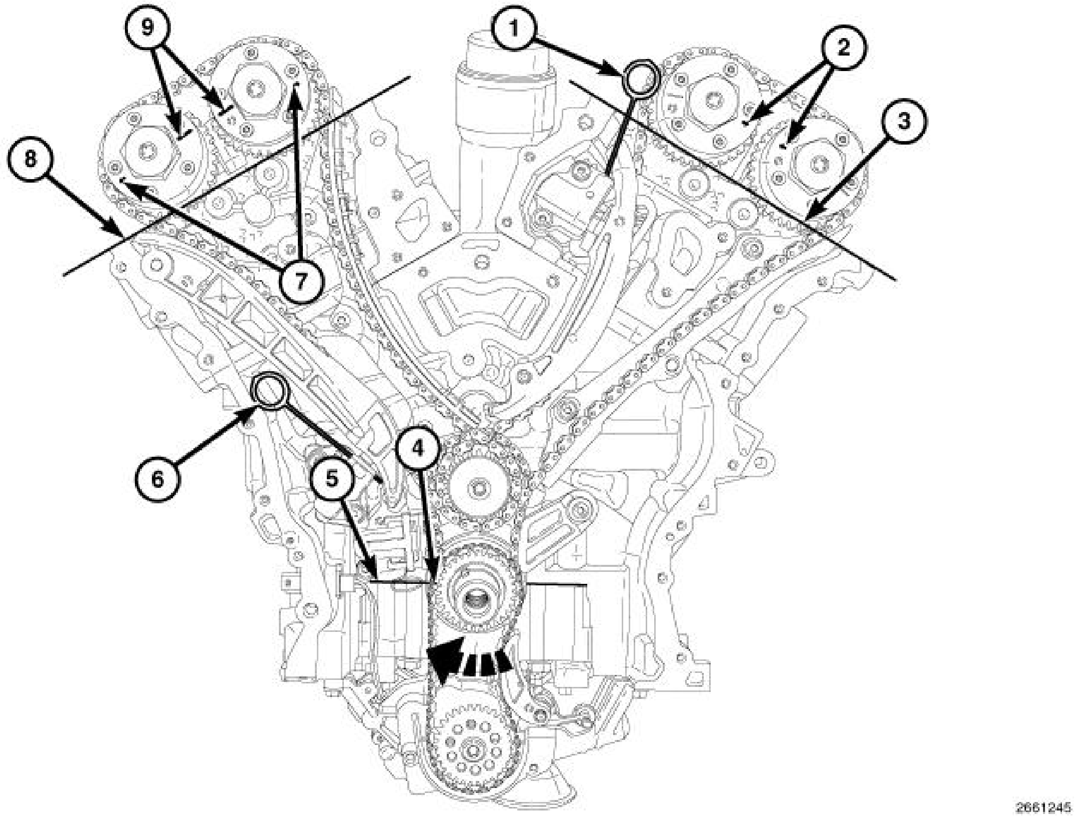
NOTE: **Take this opportunity to measure timing chain wear. Refer to VALVE TIMING, STANDARD PROCEDURE.**



[Fig. 117: Rotating Crankshaft Clockwise To Position No. 1 Piston At TDC On Exhaust Stroke]
Courtesy of CHRYSLER GROUP, LLC

CAUTION: When aligning timing marks, always rotate engine by turning the crankshaft. Failure to do so will result in valve and/or piston damage.

35. Rotate the crankshaft clockwise to place the number one piston at TDC on the exhaust stroke by aligning the dimple (4) on the crankshaft with the block/bearing cap junction (5). The left side cam phaser arrows (2) should point toward each other and be parallel to the valve cover sealing surface (3). The right side cam phaser arrows (7) should point away from each other and the scribe lines (9) should be parallel to the valve cover sealing surface (8).

CAUTION: Always reinstall timing chains so that they maintain the same direction of rotation. Inverting a previously run chain on a previously run sprocket will result in excessive wear to both the chain and sprocket.

36. Mark the direction of rotation on the timing chain using a paint pen or equivalent to aid in reassembly.

CAUTION: When the timing chains are removed and the cylinder heads are still installed, DO NOT rotate the camshafts or crankshaft without first locating the proper crankshaft position. Failure to do so will result in valve and/or piston damage.

WARNING:	**The multi-layered steel head gaskets have very sharp edges that could cause personal injury if not handled carefully.**
CAUTION:	**Do not lay the cylinder head on its gasket sealing surface, due to the design of the cylinder head gasket, any distortion to the cylinder head sealing surface may prevent the gasket from properly sealing resulting in leaks.**

NOTE: **The head gasket (1) crimps the locating dowels (2) and the dowels may pull out of the engine block when the head gasket is removed.**

49. Remove the cylinder head and gasket (1) and discard the gasket.

42. Using the sequence shown in illustration, remove the cylinder head retaining bolts.

WARNING: **The multi-layered steel head gaskets have very sharp edges that could cause personal injury if not handled carefully.**

CAUTION: **Do not lay the cylinder head on its gasket sealing surface, due to the design of the cylinder head gasket, any distortion to the cylinder head sealing surface may prevent the gasket from properly sealing resulting in leaks.**

NOTE: **The head gasket (1) crimps the locating dowels (2) and the dowels may pull out of the engine block when the head gasket is removed.**

43. Remove the cylinder head and gasket. Discard the gasket.

44. If required, remove the bolt (2) and the ignition coil capacitor (1).

CLEANING

CLEANING

CAUTION: **When cleaning cylinder head and cylinder block surfaces, DO NOT use a metal scraper because the surfaces could be cut or ground. Use ONLY a wooden or plastic scraper.**

To ensure engine gasket sealing, proper surface preparation must be performed, especially with aluminum engine components and multi-layer steel cylinder head gaskets.

NOTE: **Multi-Layer Steel (MLS) head gaskets require a scratch free sealing surface.**

1. Remove all gasket material from cylinder head and block. Refer to ENGINE GASKET SURFACE PREPARATION. Be careful not to gouge or scratch the aluminum head sealing surface.
2. Clean all engine oil passages.

   CAUTION: **Non-compressible debris such as oil, coolant or RTV sealants that are not removed from bolt holes can cause the aluminum casting to crack when tightening the bolts.**

3. Clean out the cylinder head bolt holes in the engine block.

   DO NOT USE any adhesives when installing the MLS head gaskets. The use of adhesives may cause the gasket not to seal properly and may leak. MLS gaskets are to be installed on a surface free of debris and oils.

INSPECTION

INSPECTION

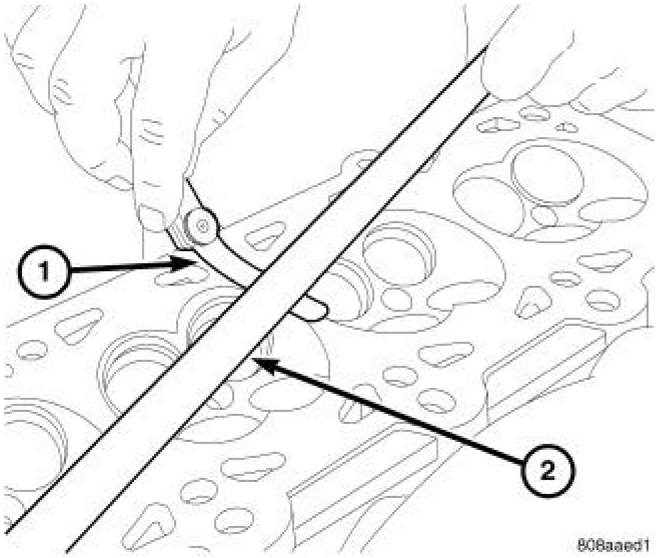

Fig. 140: Checking Cylinder Head Flatness
Courtesy of CHRYSLER GROUP, LLC

1. Check the cylinder head for warping with a straight edge (2) and feeler gauge (1).
2. Cylinder head must be flat within specification. Refer to **ENGINE SPECIFICATIONS**.
3. Verify that the valve tappets move freely in their bores and that they have been rotating.
4. Inspect camshaft bearing journals for scoring.
5. Remove carbon and varnish deposits from inside of valve guides with a reliable guide cleaner.
6. Inspect the following components and verify that they are within specification: Refer to **ENGINE SPECIFICATIONS**.
    - Camshafts
    - Valve Tappets
    - Springs
    - Valve Seats
    - Valve Guides
    - Valves

INSTALLATION

LEFT

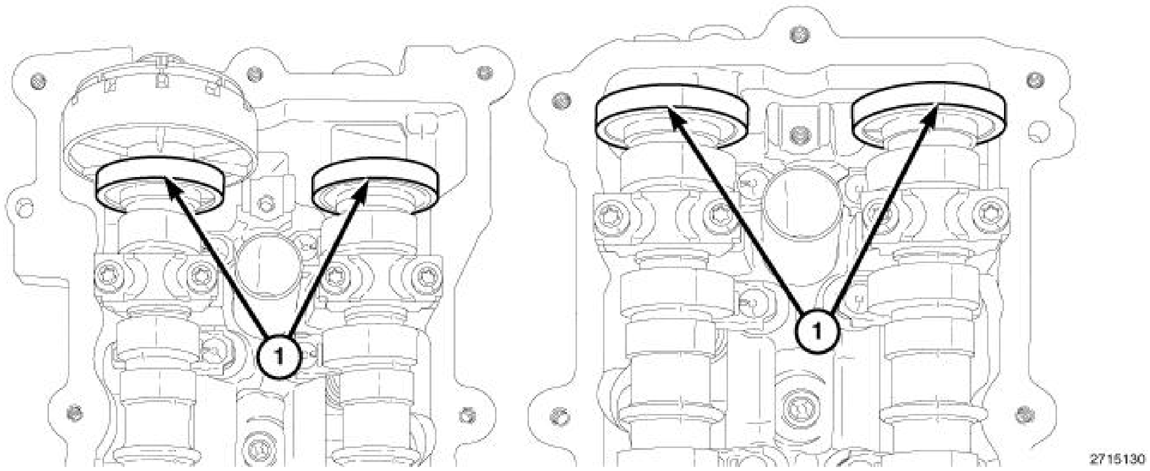

Fig. 141: Magnetic Timing Wheels

CAUTION: The magnetic timing wheels (1) must not come in contact with magnets (pickup tools, trays, etc.) or any other strong magnetic field. This will destroy the timing wheels ability to correctly relay camshaft position to the camshaft position sensor.

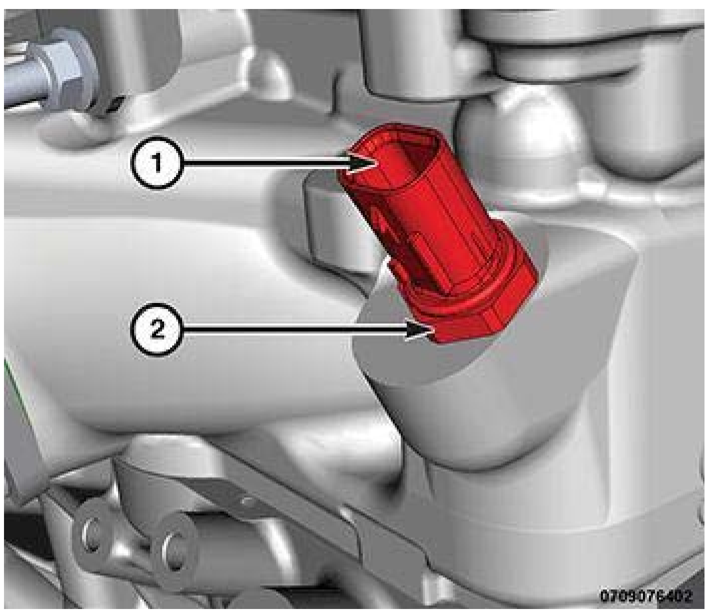

Fig. 142: ECT Sensor & Connector

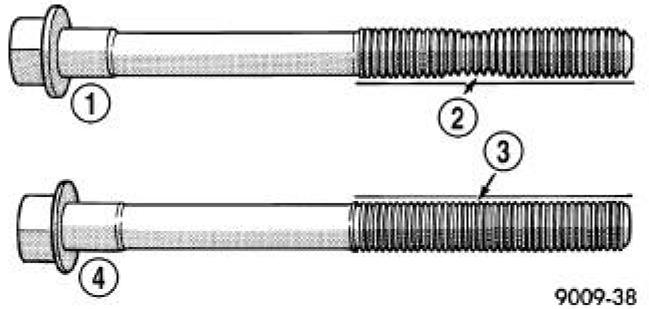
1. If removed, install the Engine Coolant Temperature (ECT) sensor (2) and tighten to the proper specification. Refer to TORQUE SPECIFICATIONS.
2. If removed, install the ignition coil capacitor and the engine wire harness retainer bracket, then tighten to the proper specification. Refer to TORQUE SPECIFICATIONS.



[Fig. 143: Checking Cylinder Head Bolts For Stretching (Necking)]

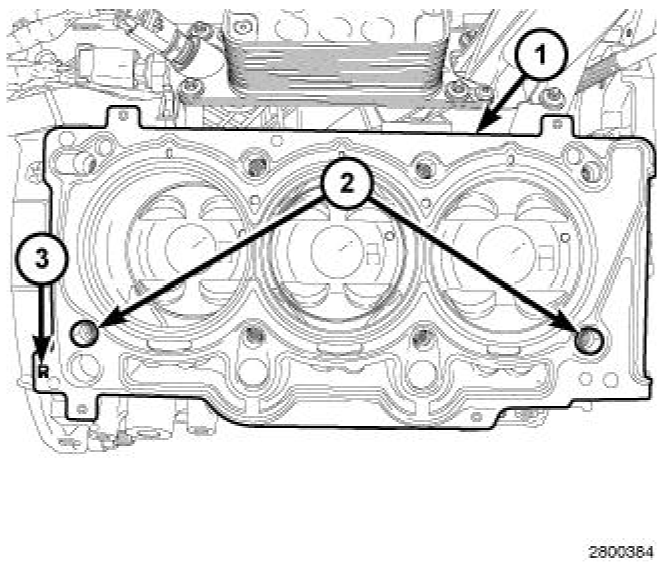
CAUTION: **The cylinder head bolts are tightened using a torque plus angle procedure. The bolts must be examined BEFORE reuse. If the threads are necked down the bolts must be replaced.**

3. Check cylinder head bolts for necking by holding a scale or straight edge against the threads. If all the threads do not contact the scale (2) the bolt must be replaced.



[Fig. 144: Head Gasket & Locating Dowels]

NOTE: **Right head gasket shown in illustration, left head gasket similar.**

CAUTION: **When cleaning cylinder head and cylinder block surfaces, DO NOT use a metal scraper because the surfaces could be cut or ground. Use ONLY a wooden or plastic scraper.**

4. Clean and prepare the gasket sealing surfaces of the cylinder head and block. Refer to ENGINE GASKET SURFACE PREPARATION.

CAUTION: **Non-compressible debris such as oil, coolant or RTV sealants that are not removed from bolt holes can cause the aluminum casting to crack when**

tightening the bolts.

5. Clean out the cylinder head bolt holes in the engine block.

WARNING: The multi-layered steel head gaskets have very sharp edges that could cause personal injury if not handled carefully.

CAUTION: The installation of the cylinder head gaskets are not interchangeable between the left and right cylinder heads. They are clearly marked (3) with "R" for right and "L" for left. They must be applied on a dry surface, without the use of any adhesives.

6. Position the new cylinder head gasket (1) onto the locating dowels (2).

7. Position the cylinder head onto the cylinder block. Make sure the cylinder head seats fully over the locating dowels.

NOTE: Do not apply any additional oil to the bolt threads.

8. Install the eight cylinder head bolts finger tight.
9. Tighten the cylinder head bolts in the sequence shown in illustration, following this 9 step torque plus angle method. The torque sequence must be used for each step. Tighten according to the following torque values:
   - Step 1: All to 30 N.m (22 ft. lbs.)
   - Step 2: All to 45 N.m (33 ft. lbs.)
   - Step 3: Retighten all to 45 N.m (33 ft. lbs.)
   - Step 4: All + 125Â° Turn (optional angle if 125Â° rotation cannot be accomplished in one motion; tighten all by turning 35Â° followed by tightening all by turning 90Â°) **Do not use a torque wrench for this step.**

- Step 5: Loosen all fasteners in reverse of sequence shown in illustration
- Step 6: All to 30 N.m (22 ft. lbs.)
- Step 7: All to 45 N.m (33 ft. lbs.)
- Step 8: Retighten all to 45 N.m (33 ft. lbs.)
- Step 9: All + 130Â° Turn (optional angle if 130Â° rotation cannot be accomplished in one motion; tighten all by turning 40Â° followed by tightening all by turning 90Â°) **Do not use a torque wrench for this step.**

NOTE: **For engine builds using a new block follow steps 1-9. For engine rebuilds (reuse block) follow step 6-9.**

CAUTION: **Do not rotate the camshafts more than a few degrees independently of the crankshaft. Valve to piston contact could occur resulting in possible valve damage. If the camshafts need to be rotated more than a few degrees, first move the pistons away from the cylinder heads by rotating the crankshaft counterclockwise to a position 30Â° before-top-dead-center. Once the camshafts are returned to their top-dead-center position, rotate the crankshaft clockwise to return the crankshaft to top-dead-center.**

NOTE: **If the hydraulic lifters are being reused, reassemble them into their original locations.**

10. If removed, install the hydraulic lifters. Refer to **LIFTER(S), HYDRAULIC, INSTALLATION**.

NOTE: **If the rocker arms are being reused, reassemble them into their original locations.**

11. Install the rocker arms and camshafts. Refer to **CAMSHAFT, ENGINE, INSTALLATION**.
12. Rotate the camshafts clockwise to TDC by positioning the alignment holes (1) vertically.

13. Install the left cam chain guide (2). Tighten bolts (4) to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
14. Install the left cam chain tensioner (5) to the cylinder head. Tighten bolts (6) to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
15. Reset the left cam chain tensioner (5) by lifting the pawl (3), pushing back the piston and installing Tensioner Pin (special tool #8514, Pins, Tensioner) (7).

    Refer to **VALVE TIMING, STANDARD PROCEDURE**.

16. Install the left tensioner arm (1).

17. Press the left intake cam phaser onto the intake camshaft, install and hand tighten the oil control valve.

CAUTION: Always reinstall timing chains so that they maintain the same direction of rotation. Inverting a previously run chain on a previously run sprocket will result in excessive wear to both the chain and sprocket.

18. Drape the left side cam chain over the left intake cam phaser and onto the idler sprocket (1) so that the arrow (3) is aligned with the plated link (2) on the cam chain.

19. While maintaining this alignment, route the cam chain around the exhaust and intake cam phasers so that the plated links are aligned with the phaser timing marks (1). Position the left side cam phasers so that the arrows (3) point toward each other and are parallel to the valve cover sealing surface (5). Press the exhaust cam phaser onto the exhaust cam, install and hand tighten the oil control valve (2).

NOTE: Minor rotation of a camshaft (a few degrees) may be required to install the camshaft phaser or phaser lock.

20. Install the LH Camshaft Phaser Lock (special tool #10202, Locks, Camshaft/Phaser) (4) and tighten the oil control valves (2, 6) to proper specification.

    Refer to **TORQUE SPECIFICATIONS**.

21. Remove the LH Camshaft Phaser Lock (special tool #10202, Locks, Camshaft/Phaser).
22. Remove the Tensioner Pin (special tool #8514, Pins, Tensioner) (1) from the left cam chain tensioner.
23. Rotate the crankshaft clockwise two complete revolutions stopping when the dimple (4) on the crankshaft is aligned the with the block/bearing cap junction (5).
24. While maintaining this alignment, verify that the arrows on the left side cam phasers (2) point toward each other and are parallel to the valve cover sealing surface (3) and that the right side cam phaser arrows (7) point away from each other and the scribe lines (9) are parallel to the valve cover sealing surface (8).

ASSEMBLY, VARIABLE VALVE TIMING, PHASER/OIL CONTROL VALVE

DESCRIPTION

DESCRIPTION

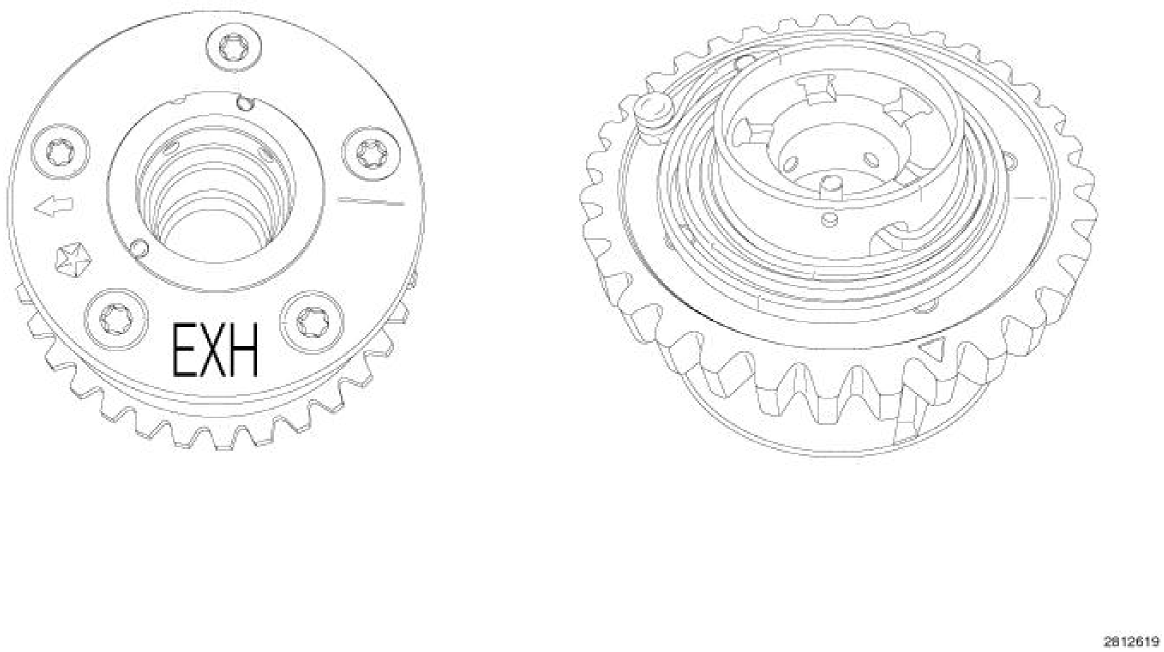

Fig. 188: Identifying Exhaust Phaser Assembly
Courtesy of CHRYSLER GROUP, LLC

The engine is equipped with Variable Valve Timing (VVT). This system adjusts the timing of all four camshafts independently using solenoids and oil control valves to direct oil pressure into the camshaft phaser assemblies. The four phasers are located on the front of the camshafts, behind the VVT solenoids, inside of the engine timing cover.

- The camshaft phaser assembly advances and/or retards camshaft timing to improve engine performance, mid-range torque, idle quality, fuel economy, and reduce emissions.
- The exhaust phasers are identified with EXH and the intake phasers are identified with INT.

- The exhaust phaser has a clockspring, the intake phaser does not.
- The camshaft sprockets are integrated with the camshaft phaser and are serviced as an assembly. Do not attempt to disassemble the phasers, they are not serviceable
- Phasers are interchangeable between the right and left cylinder heads, but should be installed in the same location as removed.

The engine has an Oil Control Valve (OCV) for each phaser. The OCV also acts as a bolt for mounting the Phaser to the camshaft. The OCVs spool valve is spring loaded and should move freely within the OCV body. The four OCVs are identical but should be installed in the same location as removed.

OPERATION

OPERATION

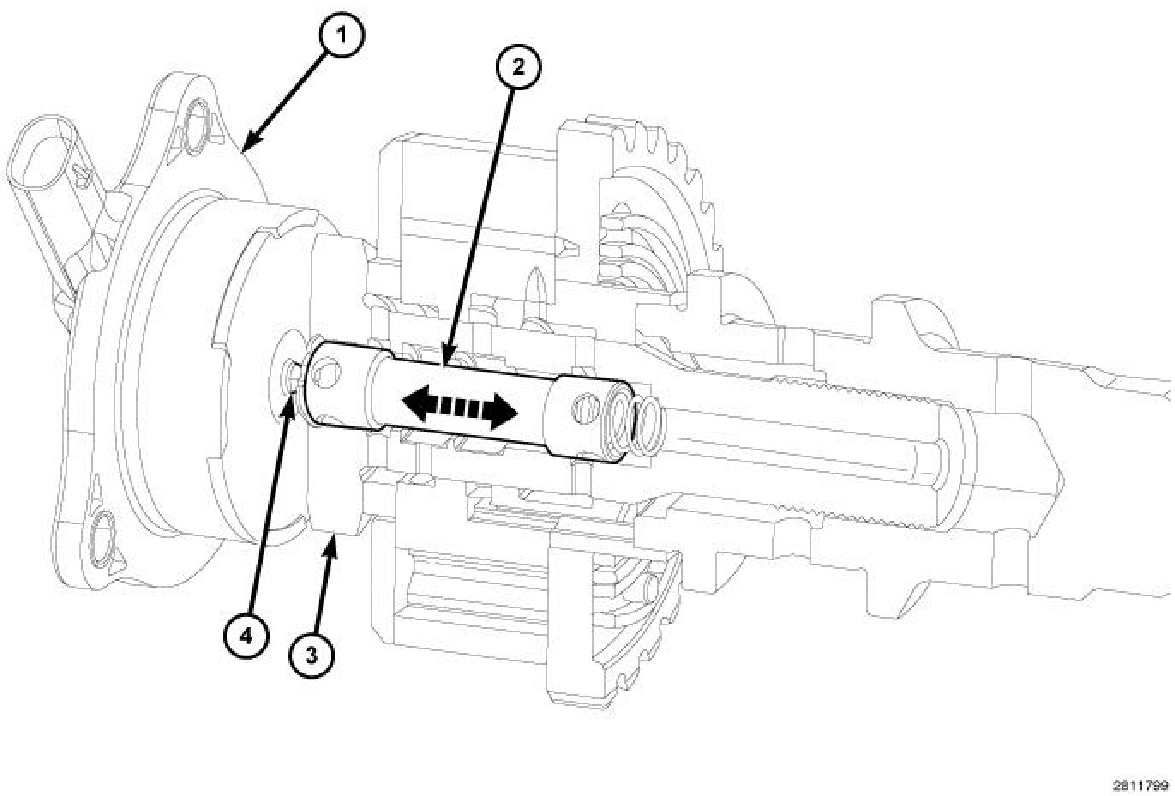

Fig. 189: Oil Control Valve (OCV), VVT Solenoid, Solenoid Pintle & Internal Spool Valve
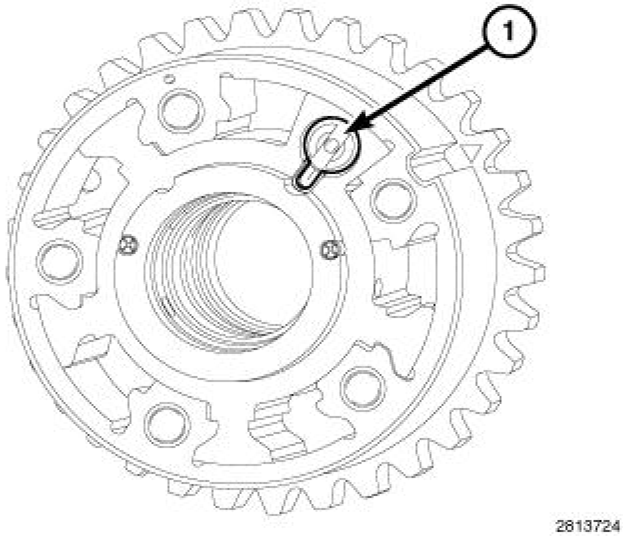
Courtesy of CHRYSLER GROUP, LLC

Each phaser position is adjusted using regulated oil pressure through the Oil Control Valve (OCV) (3). To begin phaser movement, a voltage signal is applied to the Variable Valve Timing (VVT) solenoid (1) to extend or retract the solenoid pintle (4). The pintle pushes against an internal spool valve (2) within the OCV moving the valve forward and backward to direct oil flow.



[**Fig. 190: Phasers In Lock-Pin Position**]
Courtesy of CHRYSLER GROUP, LLC

At engine startup, system oil pressure overcomes spring pressure and unlocks the phaser lock-pin (1) in preparation for phasing. The phasers remain in this position until a PCM signal is given to pulse-width modulate the VVT solenoid. At engine shutdown, as oil pressure is reduced, both Phasers return to their lock-pin position.

Because the exhaust Phaser needs to travel to a position above and beyond the standard camshaft clockwise rotation, the assistance of a clock spring is required. The intake Phaser on the other hand, simply relies on the torsional resistance from the valvetrain to push it back towards lock-pin position.

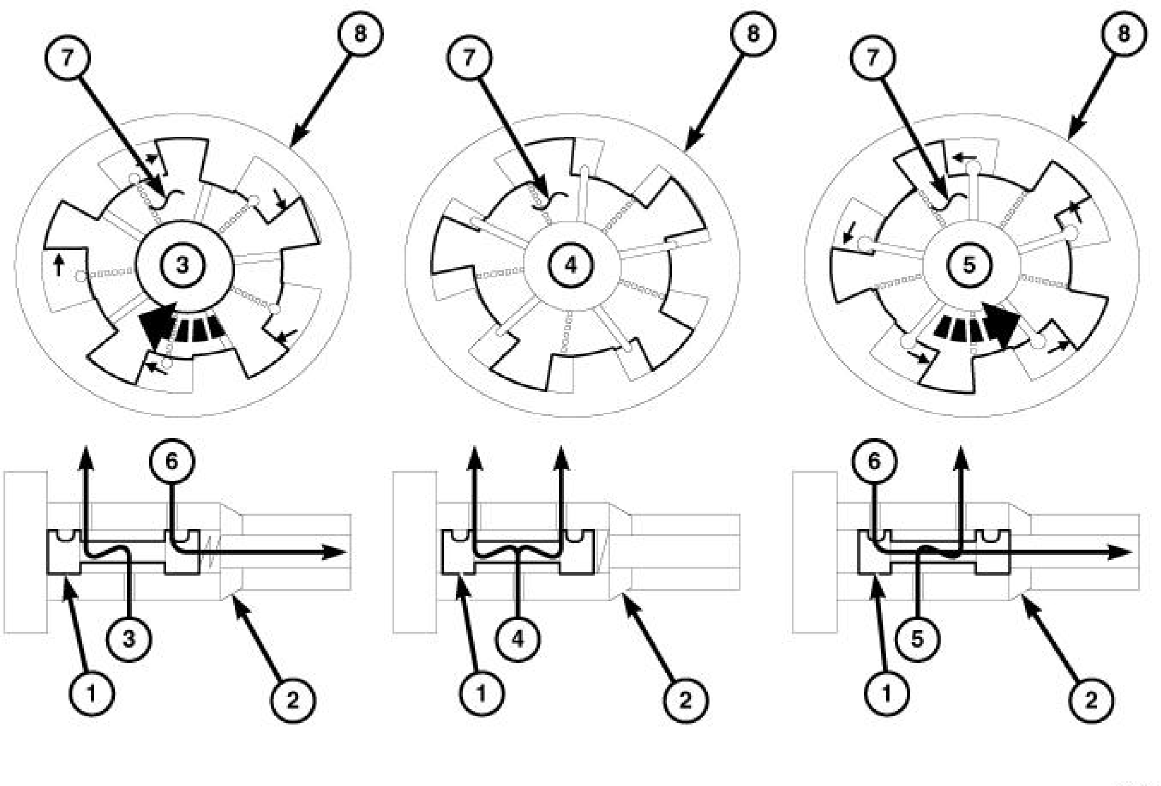


Fig. 191: Spool Valve, Vanes, OCV & Advance, Hold Or Retard Position
Courtesy of CHRYSLER GROUP, LLC

The position of the spool valve (1) inside the OCV (2) determines which ports and chambers inside the phaser are being fed, either to advance (3), hold (4) or retard (5) the timing of the phaser sprocket relative to the camshaft. The spool valve also returns oil from the chambers to the sump (6). The Camshaft Position (CMP) sensor monitors the position of the camshaft with respect to the crankshaft and provides feedback to the PCM. As oil pressure pushes against the vanes (6) of the phaser rotor, the rotor begins to move. Since this rotor is physically attached to the camshaft, rotor rotation causes the camshaft position to rotate relative to the standard sprocket (7) position.

CAUTION: The magnetic timing wheels (1) must not come in contact with magnets (pickup tools, trays, etc.) or any other strong magnetic field. This will destroy the timing wheels ability to correctly relay camshaft position to the camshaft position sensor.

1. Remove the left cylinder head cover. Refer to **COVER(S), CYLINDER HEAD, REMOVAL**.
2. Remove the right side spark plugs. Refer to **SPARK PLUG, REMOVAL** .

CAUTION: When aligning timing marks, always rotate engine by turning the crankshaft. Failure to do so will result in valve and/or piston damage.

3. Mount the Dial Indicator Set (special tool #C-3339A, Set, Dial Indicator) (1) to a stationary point on the engine, such as the number three cylinder ignition coil mount. Position the indicator probe into the number one cylinder, rotate the crankshaft clockwise (as viewed from the front) to place the number one cylinder piston at top-dead-center on the exhaust stroke and set the indicator dial to zero.

- The indicator dial is set to **ZERO** when the right side number one cylinder piston is positioned at top-dead-center on the exhaust stroke.
- The **SCRIBE LINES** (3) on the left side cam phasers face away from each other.
- The **ARROWS** (4) on the left side cam phasers point toward each other and are parallel to the cylinder head cover mounting surface.
- There are twelve chain pins (2) **BETWEEN** the exhaust cam phaser triangle marking (1) and the intake cam phaser circle marking (3).

10. If the engine timing is not correct, repeat this procedure.
11. Install the left cylinder head cover. Refer to COVER(S), CYLINDER HEAD, INSTALLATION.
12. Install the right side spark plugs. Refer to SPARK PLUG, INSTALLATION .
13. Connect the negative battery cable.
14. Start the engine and perform the following Powertrain Verification Tests: Refer to appropriate Engine Electrical Diagnostics article.
    - Cam/Crank Variation Relearn

CAMSHAFT, ENGINE

DESCRIPTION

DESCRIPTION

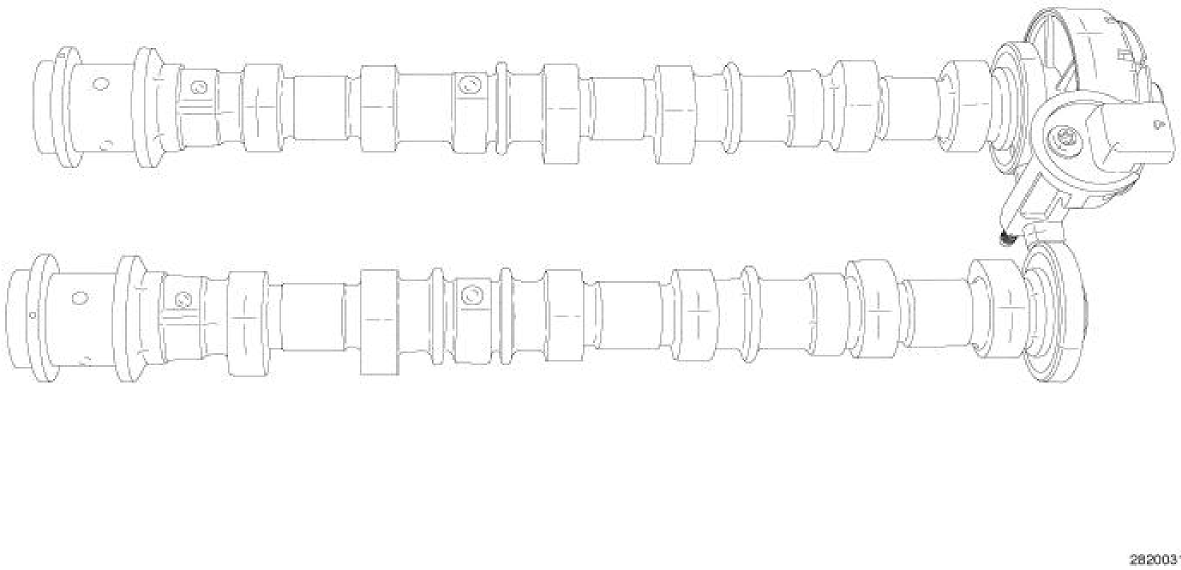

Fig. 221: Dual Over Head Camshaft (DOHC) Configuration
Courtesy of CHRYSLER GROUP, LLC

The Pentastar engine uses a Dual Over Head Camshaft (DOHC) configuration.

- The camshafts are a nodular cast iron design.
- Each camshaft has a pressed on magnetic timing wheel that is magnetically encoded.
- The two Camshaft Position (CMP) sensors are located between the timing wheels.
- Attached to the rear of the right exhaust camshaft is a centrifuge which is part of the crankcase ventilation system.

The centrifuge is used to separate oil droplets from the crankcase gases before they enter the PCV valve. Four bearing journals are machined into the camshaft. Camshaft end play is controlled by two thrust walls that border the nose piece journal.

OPERATION

OPERATION

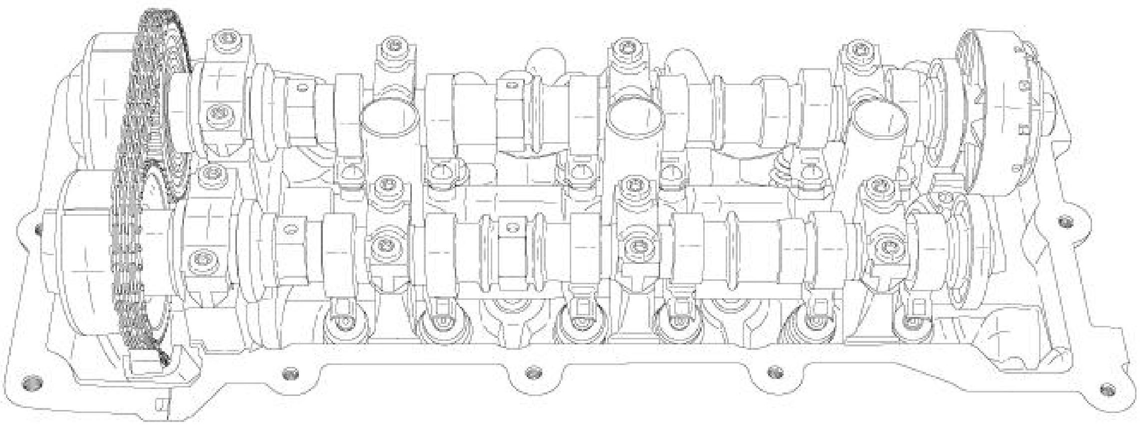

Fig. 222: Right Hand Camshafts
Courtesy of CHRYSLER GROUP, LLC

NOTE: RH camshafts shown in illustration, LH camshafts similar.

The camshaft has precisely machined (egg shaped) lobes to provide accurate valve timing and duration. The camshaft is driven by the crankshaft via drive sprockets and chains.

STANDARD PROCEDURE

CAMSHAFT END PLAY

1. Remove the cylinder head cover. Refer to COVER(S), CYLINDER HEAD, REMOVAL.

   NOTE: Cylinder #1 or #4 must be used when checking for Top Dead Center (TDC).

   NOTE: Right intake camshaft shown in illustration, other camshafts similar.

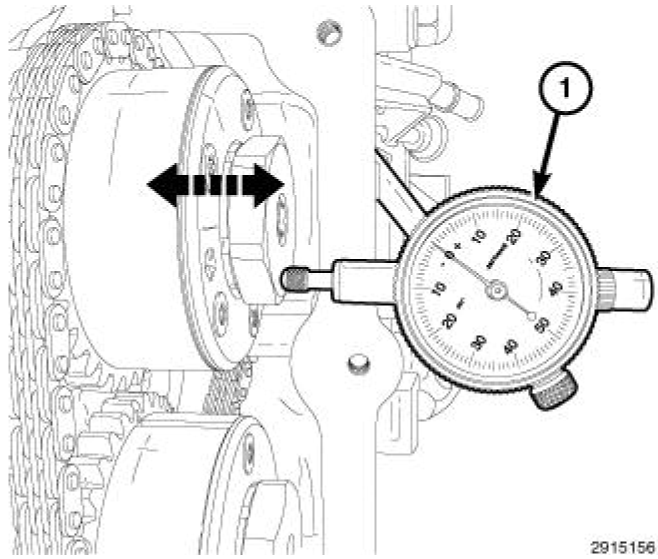

Fig. 223: Mount Dial Indicator Set To A Stationary Point At Front Of Engine
Courtesy of CHRYSLER GROUP, LLC

2. Mount the Dial Indicator Set (special tool #C-3339A, Set, Dial Indicator) (1) to a stationary point at the front of the engine. Place the probe perpendicular against the Oil Control Valve (OCV) of the camshaft.
3. Move the camshaft all the way to the rear of its travel.
4. Zero the dial indicator.
5. Move the camshaft forward to the limit of travel and read the dial indicator. Compare the measured end play to the specification. Refer to **ENGINE SPECIFICATIONS**.

REMOVAL

LEFT

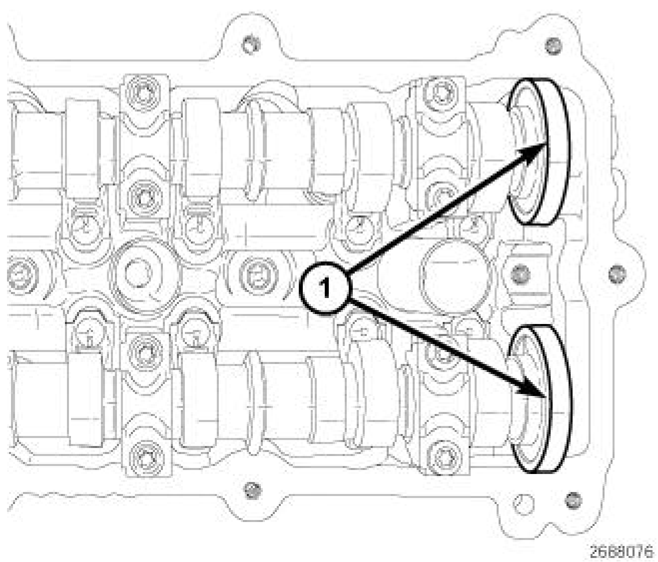

Fig. 224: Magnetic Timing Wheels
Courtesy of CHRYSLER GROUP, LLC

CAUTION: **The magnetic timing wheels (1) must not come in contact with magnets (pickup tools, trays, etc.) or any other strong magnetic field. This will destroy the timing**

wheels ability to correctly relay camshaft position to the camshaft position sensor.

CAUTION: When the timing chain is removed and the cylinder heads are still installed, Do not forcefully rotate the camshafts or crankshaft independently of each other. Severe valve and/or piston damage can occur.

CAUTION: DO NOT STAMP OR STRIKE THE CAMSHAFT BEARING CAPS. SEVERE DAMAGE WILL OCCUR TO THE BEARING CAPS.

1. Remove the variable valve timing assembly. Refer to ASSEMBLY, VARIABLE VALVE TIMING, PHASER/OIL CONTROL VALVE, REMOVAL.

NOTE: Camshaft bearing caps should have been marked during engine manufacturing. For example, the number one exhaust camshaft bearing cap is marked "1E->". The caps should be installed with the notch forward.

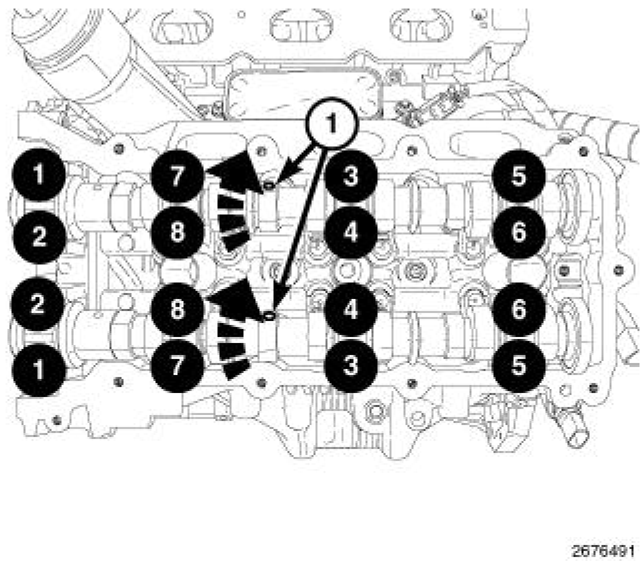

Fig. 225: Camshaft Bearing Cap Bolts Removal Sequence - Left
Courtesy of CHRYSLER GROUP, LLC

2. Rotate the camshafts counterclockwise to position the alignment holes (1) **approximately 30Ā° before top-dead-center** . This places the camshafts in the neutral position (no valve load).
3. Loosen the camshaft bearing cap bolts in the sequence shown in illustration.

NOTE: When the camshaft is removed the rocker arms may slide downward, mark the rocker arms before removing the camshaft.

4. Remove the camshaft bearing caps and the camshafts.

RIGHT

CAUTION: **The magnetic timing wheels (1) must not come in contact with magnets (pickup tools, trays, etc.) or any other strong magnetic field. This will destroy the timing wheels ability to correctly relay camshaft position to the camshaft position sensor.**

CAUTION: **When the timing chain is removed and the cylinder heads are still installed, Do not forcefully rotate the camshafts or crankshaft independently of each other. Severe valve and/or piston damage can occur.**

CAUTION: **DO NOT STAMP OR STRIKE THE CAMSHAFT BEARING CAPS. SEVERE DAMAGE WILL OCCUR TO THE BEARING CAPS.**

1. Remove the variable valve timing assembly. Refer to ASSEMBLY, VARIABLE VALVE TIMING, PHASER/OIL CONTROL VALVE, REMOVAL.

2. Camshaft bearing caps should have been marked during engine manufacturing. For example, the number one exhaust camshaft bearing cap is marked "1E->". The caps should be installed with the notch forward.

NOTE: **Loosen the camshaft bearing cap bolts in the sequence shown in illustration.**

NOTE: **When the camshaft is removed the rocker arms may slide downward, mark the rocker arms before removing the camshaft.**

3. Remove the camshaft bearing caps and the camshafts.

INSPECTION

INSPECTION

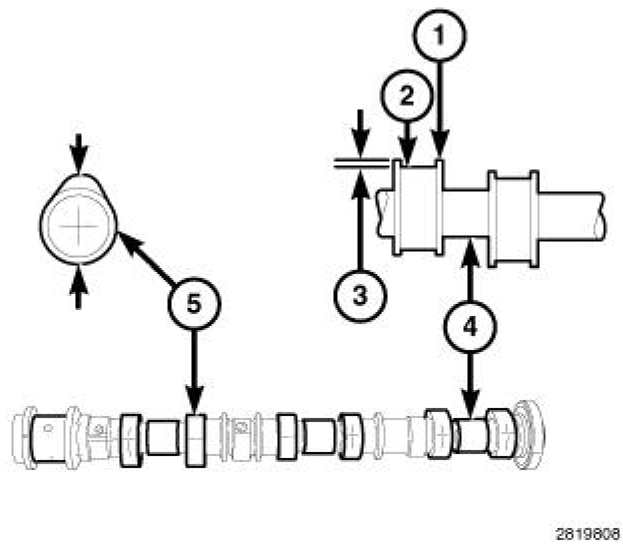

Fig. 228: Inspecting Camshaft Bearing Journals & Cam Lobes
Courtesy of CHRYSLER GROUP, LLC

NOTE: **RH intake camshaft shown in illustration, other camshafts similar.**

1. Inspect camshaft bearing journals (4) for damage and binding. If journals are binding, check the cylinder head for damage. Also check cylinder head oil holes for clogging.
2. Check the surface of the cam lobes (5) for abnormal wear (3). Measure and compare the unworn area (1) to the worn area (2). Replace camshafts that are not within specification. Refer to ENGINE SPECIFICATIONS.

INSTALLATION

LEFT

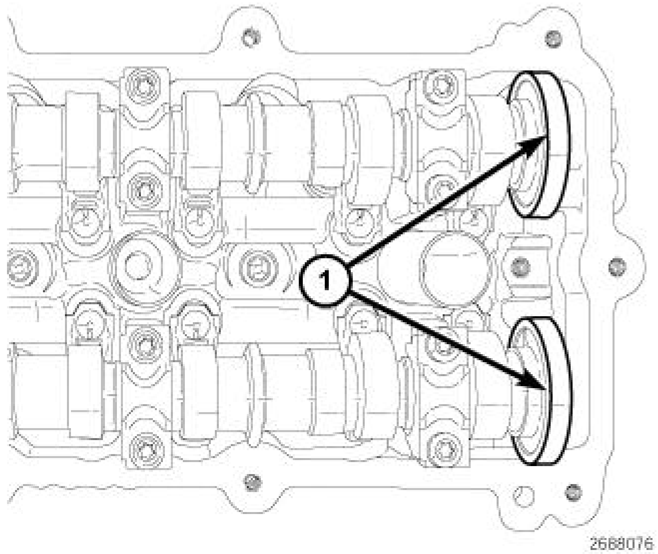

Fig. 229: Magnetic Timing Wheels

1. Lubricate the camshaft journals with clean engine oil.

CAUTION: Do not rotate the camshafts more than a few degrees independently of the crankshaft. Valve to piston contact could occur resulting in possible valve damage. If the camshafts need to be rotated more than a few degrees, first move the pistons away from the cylinder heads by rotating the crankshaft counterclockwise to a position 30Â° before-top-dead-center. Once the camshafts are returned to their top-dead-center position, rotate the

crankshaft clockwise to return the crankshaft to top-dead-center.

2. Install the left side camshaft(s) with the alignment holes (1) positioned approximately 30Â° before top-dead-center. This will place the camshafts at the neutral position (no valve load) easing the installation of the camshaft bearing caps.

   Caps are identified numerically (1 through 4), intake or exhaust (I or E) and should be installed from the front to the rear of the engine. All caps should be installed with the notch forward so that the stamped arrows (<) on the caps point toward the front of the engine.

3. Verify the rocker arms are aligned to the cam lobe Refer to **ROCKER ARM, VALVE, INSTALLATION**.
4. Install the camshaft bearing caps and tighten the bolts finger tight.
5. Using the tightening sequence shown in illustration, tighten the bearing cap bolts to 10 N.m (89 in. lbs.).

6. Rotate the camshafts clockwise to top-dead-center by positioning the alignment holes (1) vertically.
7. Install the variable valve timing assembly. Refer to **ASSEMBLY, VARIABLE VALVE TIMING, PHASER/OIL CONTROL VALVE, INSTALLATION**.

NOTE: **The Cam/Crank Variation Relearn procedure must be performed using the scan tool anytime there has been a repair/replacement made to a powertrain system. For example: flywheel, valvetrain, camshaft and/or crankshaft sensors or components.**

COVER(S), CYLINDER HEAD

DESCRIPTION

DESCRIPTION

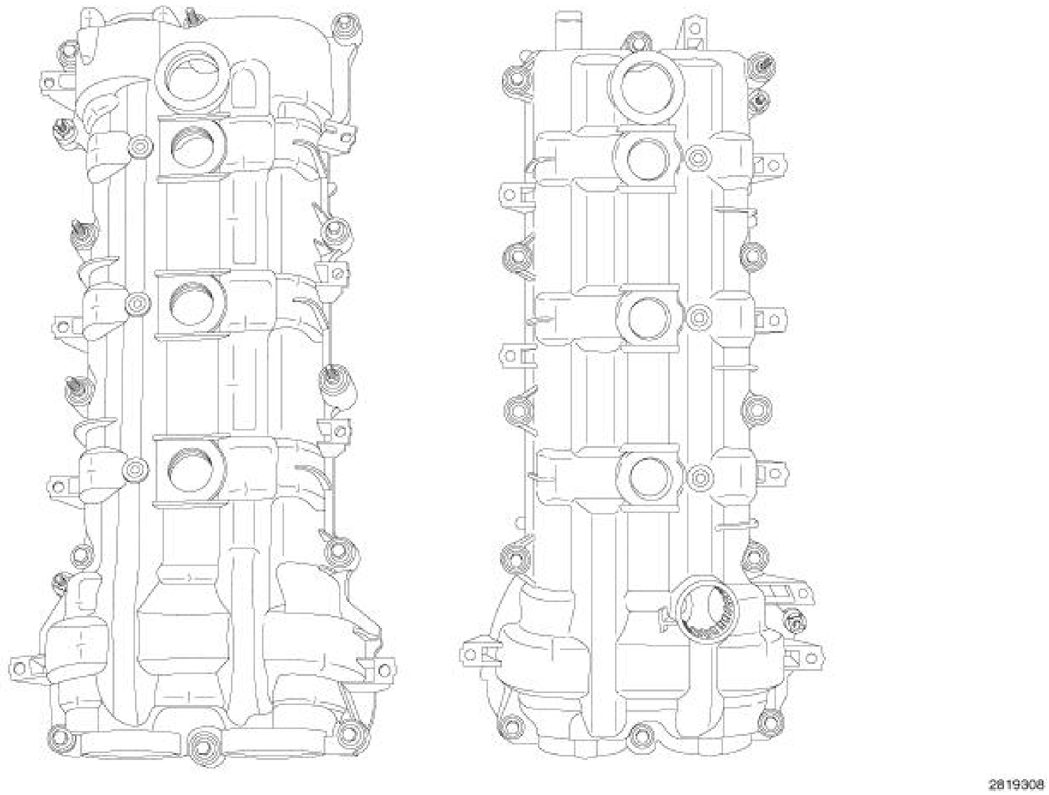

Fig. 235: Cylinder Head Covers
Courtesy of CHRYSLER GROUP, LLC

The cylinder head covers are made of a carbon and fiberglass composite.

- The cylinder head covers are not interchangeable from side-to-side.
- The cylinder head covers are sealed with a press-in-place gasket that is designed to isolate the cover from the cylinder head for improved Noise Vibration and Harshness (NVH).
- There are two dowel pins on the outboard side of the cover flange to locate the cover to holes in the cylinder head.
- Room Temperature Vulcanizing silicone (RTV) is used to seal the T-joint at the timing cover, cylinder head and cylinder head cover.

4. Clean the timing engine timing cover, cylinder head and cylinder head cover mating surfaces with isopropyl alcohol in preparation for sealant application.

CAUTION: **Engine assembly requires the use of a unique sealant that is compatible with engine oil. Using a sealant other than MoparÃ® Threebond Engine RTV Sealant may result in engine fluid leakage.**

CAUTION: **Following the application of MoparÃ® Threebond Engine RTV Sealant to the gasket surfaces, the components must be assembled within 20 minutes and the attaching fasteners must be tightened to specification within 45 minutes. Prolonged exposure to the air prior to assembly may result in engine fluid leakage.**

5. Apply a 2 to 3 mm wide bead of MoparÃ® Threebond Engine RTV Sealant (1) to the two engine timing cover to cylinder head T-joints as shown in illustration.

LIFTER(S), HYDRAULIC

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - HYDRAULIC LIFTER(S) NOISE DIAGNOSIS

Proper noise diagnosis is essential in locating the source of an NVH complaint. Locating a lash adjuster (tappet) type noise can sometimes be difficult. As a result, an initial misdiagnosis may occur.

Refer to the following LASH ADJUSTER (TAPPET) NOISE CHART for possible causes and correction of a lash adjuster (tappet) type noise.

LASH ADJUSTER (TAPPET) NOISE CHART

POSSIBLE CAUSES	CORRECTION
1. Engine oil level-too high or too low. This may allow aerated oil to enter the adjusters and cause them to be spongy.	1. Check and correct the engine oil level.
2. Insufficient running time after rebuilding a cylinder head.	2. Low speed running of up to 1 hour may be required to fully evacuate trapped air from the valve train system. During this time, turn engine off and let set for a few minutes before restarting. Repeat this several times after engine has reached normal operating temperature.
3. Air trapped in the lash adjuster (after 1 hour of run time).	3. See below:
	(a) Check the lash adjusters for sponginess while installed in the cylinder head. Press down on the rocker arm in a manner that could collapse the lash adjuster. Normal adjusters should feel very firm. Very spongy adjusters can be bottomed out easily.
	(b) If the lash adjuster(s) are still spongy, replace the lash adjuster(s). Refer to **LIFTER(S), HYDRAULIC, REMOVAL**.
4. Low oil pressure.	4. See below:
	(a) Check and correct the engine oil level.
	(b) Check the engine oil pressure. Refer to **DIAGNOSIS AND TESTING**.
	(c) Check for excessive main bearing clearance and correct specification. Refer to **STANDARD PROCEDURE**.
	(d) Check for a worn oil pump. Refer to **INSPECTION**.
	Check the camshaft journals and the bearing bores for abnormal wear patterns, scoring, grooving, fatigue, pitting or a foreign material. Refer to **CAMSHAFT, ENGINE, REMOVAL**.

POSSIBLE CAUSES	CORRECTION
5. A plugged oil restrictor in the oil passages to the cylinder head(s).	5. Check the cylinder head oil passages for blockage. Clean or replace as necessary.
6. Worn valve guide(s).	6. Measure the valve stem-to-guide clearance. Refer to **VALVES, INTAKE AND EXHAUST, INSPECTION**.
7. Rocker arm loose, adjuster stuck or at maximum extension and still leaves lash in the system.	7. See below:
-	(a) Check the camshaft journal and lobe for abnormal wear patterns, scoring, grooving, fatigue, pitting or a foreign material. Refer to **CAMSHAFT, ENGINE, REMOVAL**.
-	(b) Check the rocker arm(s) for proper alignment to the camshaft lobe(s) and valve stem(s). Refer to **ROCKER ARM, VALVE, REMOVAL**.
-	(c) Check the lash adjuster(s) for proper operation and replace as necessary. Refer to **LIFTER(S), HYDRAULIC, REMOVAL**.
8. Air ingested into the engine oil due to a broken or cracked oil pump pickup tube.	8. Check the pickup tube and replace as necessary. Refer to **PICK-UP, OIL PUMP, REMOVAL**.
9. Faulty lash adjuster.	9. Replace the lash adjuster(s). Refer to **LIFTER(S), HYDRAULIC, REMOVAL**.

REMOVAL

REMOVAL

NOTE: **The LH cylinder head hydraulic lifters are shown in illustration, the RH cylinder head hydraulic lifters are similar.**

1. Disconnect and isolate the negative battery cable. If equipped with an Intelligent Battery Sensor (IBS), disconnect the IBS connector first before disconnecting the negative battery cable.
2. Remove the camshaft(s). Refer to **CAMSHAFT, ENGINE, REMOVAL**.

   NOTE: **If the rocker arms are to be reused, identify their positions so that they can be reassembled into their original locations.**

3. Remove the rocker arm(s). Refer to **ROCKER ARM, VALVE, REMOVAL**.

NOTE: The LH cylinder head hydraulic lifters are shown in illustration, the RH cylinder head hydraulic lifters are similar. If the hydraulic lifters are being reused, reassemble them into their original locations.

1. Verify that the hydraulic lifters are at least partially full of oil. There should be little or no plunger travel

when the hydraulic lifter is depressed.

2. Install the hydraulic lifter(s) (1).

NOTE: **If the rocker arms are being reused, reassemble them into their original locations.**

3. Install the rocker arm(s). Refer to **ROCKER ARM, VALVE, INSTALLATION**.
4. Install the camshaft(s), phasers, cylinder head cover(s) and upper intake manifold. Refer to **CAMSHAFT, ENGINE, INSTALLATION**.
5. Connect the negative battery cable. If equipped with an Intelligent Battery Sensor (IBS), connect the IBS connector.

ROCKER ARM, VALVE

DESCRIPTION

DESCRIPTION

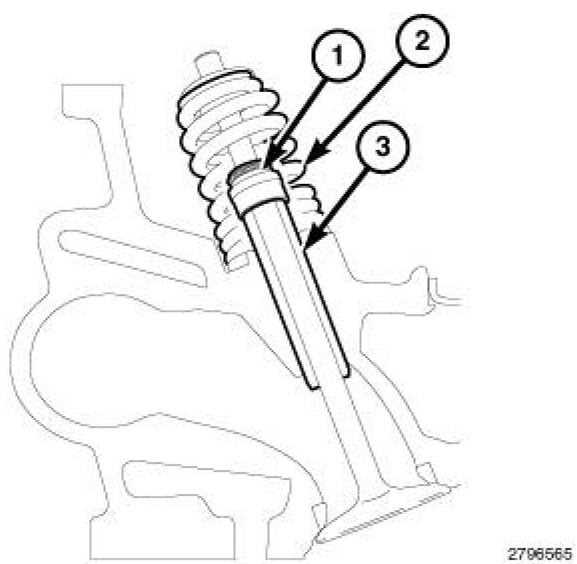
SEAL(S), VALVE GUIDE

DESCRIPTION

DESCRIPTION



[Fig. 285: Valve Stem Oil Seal, Valve Spring & Valve Guide]
Courtesy of CHRYSLER GROUP, LLC

The valve stem oil seals (1) are made of elastomer over-molded steel in a non-integrated type guide mounted configuration. The seal is not held in place by the valve spring (2). The valve stem seals are not reusable if removed from the valve guides (3), they must be replaced. Always coat the valve seals with clean engine oil before installing the valves.

REMOVAL

REMOVAL

NOTE: If the springs are to be reused, identify their positions so that they can be reassembled into their original locations.

1. Remove the valve spring(s) (2). Refer to **SPRING(S), VALVE, REMOVAL**.

NOTE: **Ensure that the garter spring (2) is intact around the top of the valve guide seal (3). Number 5 cylinder exhaust valve guide seal shown in illustration, all other valves similar.**

3. Apply engine oil to the lip of the valve guide seal (3). Install the valve guide seal (3) over the valve stem. Using an appropriate driver (1), push the seal firmly and squarely over the valve guide. **Do Not Force** the seal against the top of guide.

NOTE: **If the valve springs are being reused, reassemble them into their original locations.**

4. Install the valve spring(s). Refer to **SPRING(S), VALVE, INSTALLATION**.

SPRING(S), VALVE

DESCRIPTION

DESCRIPTION

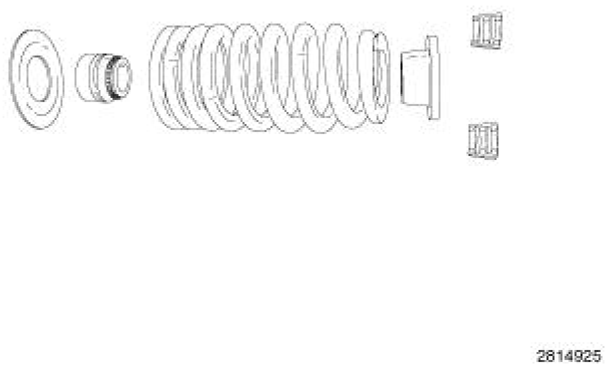

Fig. 290: Valve Spring Components
Courtesy of CHRYSLER GROUP, LLC

The valve springs are a beehive design and made from high strength chrome silicon steel. The springs are common for intake and exhaust applications. Valve guide seals are rubber overmolded on a steel support cylinder with a garter spring at the seal lip. The seals are not integrated with the valve spring seat. The valve spring seat is a flat steel washer. The steel valve spring retainers are designed for use with beehive springs and the valve spring retainer locks are a three bead Butt type design.

CAUTION: The magnetic timing wheels (1) must not come in contact with magnets (pickup tools, trays, etc.) or any other strong magnetic field. This will destroy the timing wheels ability to correctly relay camshaft position to the camshaft position sensor.

1. Disconnect and isolate the negative battery cable.

2. If removing the LH exhaust valve springs, recover the refrigerant from the refrigerant system and remove the A/C suction and liquid line assembly. Refer to **LINE, A/C SUCTION, REMOVAL** .

3. If removing the LH exhaust valve springs, remove the nut (1) and bolt (4) from the support brackets of the heater core return tube (3) and reposition the tube.
4. Remove both cylinder head covers. Refer to **COVER(S), CYLINDER HEAD, REMOVAL**.

NOTE: **Only remove the camshafts from one head at a time. The opposite head must remain assembled in order to lock the crankshaft against rotation.**

5. Remove the camshaft(s). Refer to **CAMSHAFT, ENGINE, REMOVAL**.

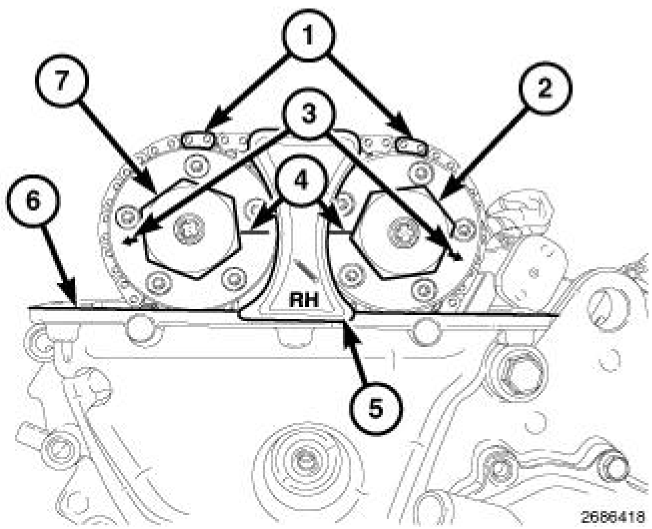

Fig. 294: Phaser Timing Marks, Oil Control Valves & RH Camshaft Phaser Lock
Courtesy of CHRYSLER GROUP, LLC

NOTE: **RH camshaft phaser lock shown in illustration, LH camshaft phaser lock similar.**

CAUTION: **Air pressure applied to the cylinder holds the valves in place. This air pressure also has a tendency to force the piston down and rotate the crankshaft. Do not allow the crankshaft to rotate. Crankshaft rotation may damage the timing chain or front timing cover and affect camshaft timing.**

7. If removing the LH camshafts, install the RH Camshaft Phaser Lock (special tool #10202, Locks, Camshaft/Phaser) -1 (5) to lock the crankshaft against rotation. If removing the RH camshafts, install the LH Camshaft Phaser Lock (special tool #10202, Locks, Camshaft/Phaser) -2 to lock the crankshaft against rotation.
8. Remove the spark plug. Refer to **SPARK PLUG, REMOVAL** .

NOTE: **Number 4 cylinder intake valve spring compression shown in illustration, all other valves similar.**

9. Install Valve Spring Compressor (special tool #MD998772A, Compressor, Valve Spring) (2) onto the cylinder head.
10. Install a spark plug adapter attached to a regulated shop air supply (1). Pressurize the cylinder being serviced to 620.5 - 689 kPa (90 - 100 psi) to hold the valves in place.

CAUTION: **Air pressure must be maintained as long as the valve springs are removed to prevent the valves from dropping into the cylinders.**

11. Using Valve Spring Compressor Adapter (special tool #10224, Adapter, Valve Spring) (3), compress valve spring (4) and remove valve retaining locks (5).

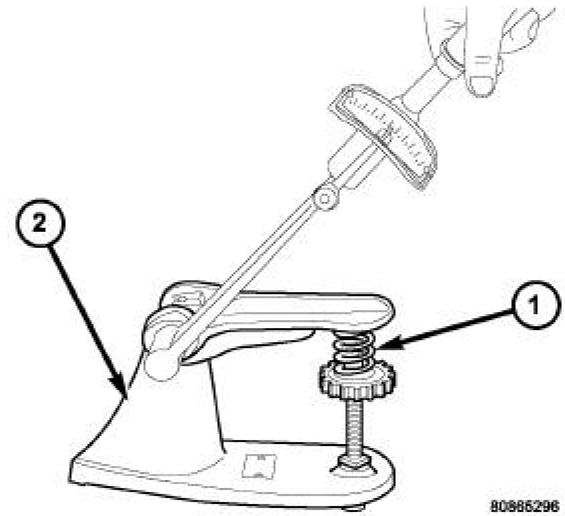
INSPECTION

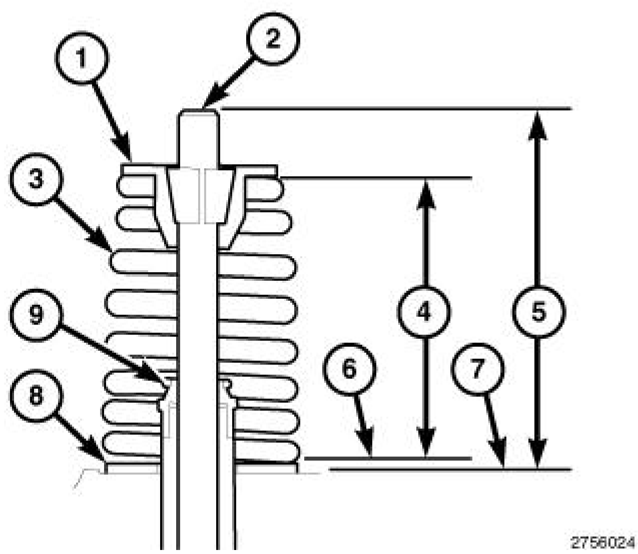
INSPECTION



[Fig. 301: Testing Valve Spring](#)
Courtesy of CHRYSLER GROUP, LLC

When valves have been removed for inspection, reconditioning or replacement, valve springs should be checked against specifications for free-length, spring force and spring installed height. Refer to **ENGINE SPECIFICATIONS**.

Spring force can be measured with a test fixture (2). Follow the tool manufactures instructions. Replace any springs that do not meet specifications.



[Fig. 302: Checking Valve Spring Installed Height](#)
Courtesy of CHRYSLER GROUP, LLC

Installed height of the valve spring must be checked with the valve assembled into the cylinder head. Refer to **SPRING(S), VALVE, INSTALLATION**.

If the valves or valve seats have been refinished and the installed valve spring height (4) is greater than 40.0 mm (1.575 in.). Install a second spring seat (8) in the head counter bore under the original valve spring seat to bring the spring height within specification. Make sure the measurement is taken from the top of spring seat (6) to the bottom surface of spring retainer (1).

4. If the valves or valve seats have been refinished, check the installed height of the valve springs (4). If the installed valve spring height (4) is greater than 40.0 mm (1.575 in.), install an additional spring seat (8) in the head counterbore under the original valve spring seat (8) to bring the spring height back within specification. Make sure the measurement is taken from the top of spring seat (6) to the bottom surface of spring retainer (1).

5. Install the cylinder head(s). Refer to CYLINDER HEAD, INSTALLATION.

CAUTION: Spark plug torque is critical and must not exceed the specified value. Overtightening stretches the spark plug shell reducing its heat transfer capability resulting in possible catastrophic engine failure.

6. Install the spark plug. Refer to **SPARK PLUG, INSTALLATION** .
7. If required, install a new spark plug tube seal (2).
8. Install the cylinder head cover(s). Refer to **COVER(S), CYLINDER HEAD, INSTALLATION**.

VALVES, INTAKE AND EXHAUST

DESCRIPTION

DESCRIPTION

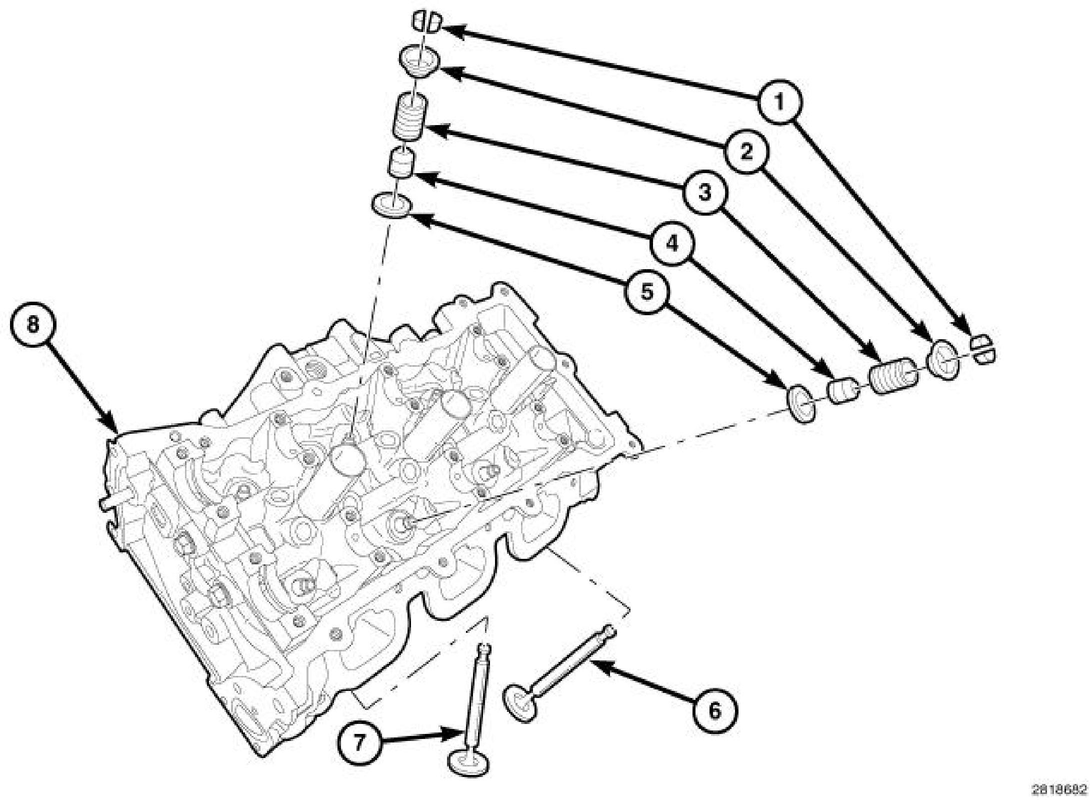

Fig. 320: Intake Valve & Exhaust Valve Component Configuration
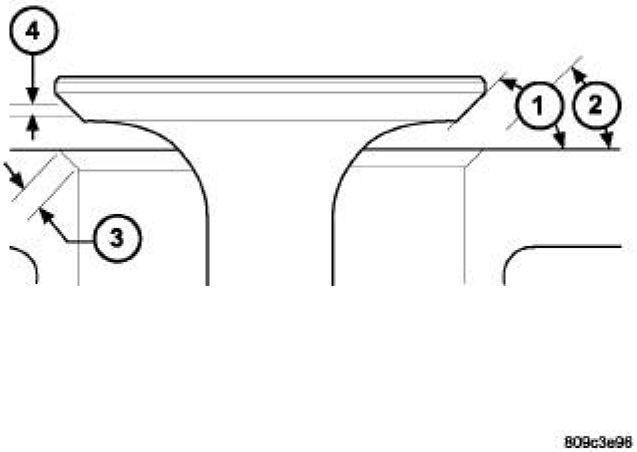
Courtesy of CHRYSLER GROUP, LLC

The intake valve (6) is made from a one piece forged heat resistant (martensitic) steel. The exhaust valve (7) is a two piece construction with a forged (austenitic) head welded to the (martensitic) stem. Both valves have a nitrided surface treatment to prevent scuffing except at the tip and lock grooves. The four valves per cylinder are actuated by roller rocker arms, which pivot on stationary lash adjusters. All valves use three bead lock keepers (1) to retain springs (3) and to promote valve rotation.

STANDARD PROCEDURE

REFACING INTAKE AND EXHAUST VALVES

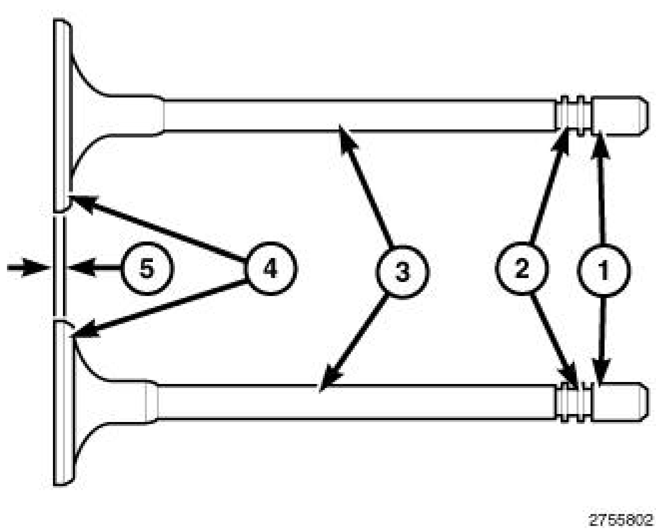


[Fig. 321: Valve Face & Seat](#)
Courtesy of CHRYSLER GROUP, LLC

1 - SEAT WIDTH
2 - FACE ANGLE
3 - SEAT ANGLE
4 - SEAT CONTACT AREA

The intake and exhaust valves have a 45.25 Â± 0.25 degree face angle (1). The valve seats (2) have a 44.75 Â± 0.25 degree face angle.

VALVES



[Fig. 322: Inspecting Valve Margin](#)

Inspect the remaining margin (5) after the valves are refaced. Refer to **ENGINE SPECIFICATIONS**.

VALVE SEATS

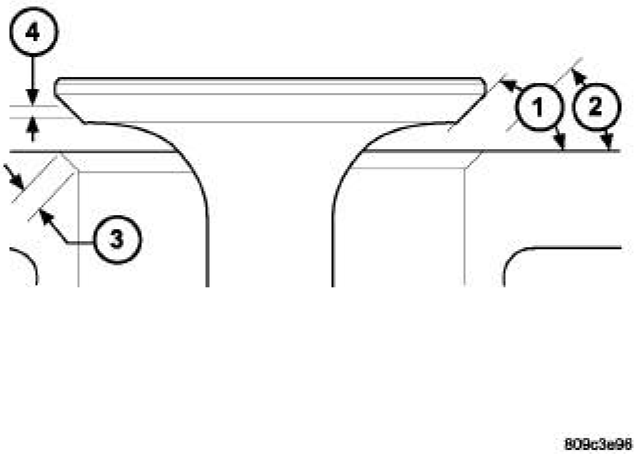

Fig. 323: Valve Face & Seat
Courtesy of CHRYSLER GROUP, LLC

1 - SEAT WIDTH
2 - FACE ANGLE
3 - SEAT ANGLE
4 - SEAT CONTACT AREA

NOTE: When refacing the valve seats, it is important that the correct size valve guide pilot be used for the reseating stones. A true and complete surface must be obtained.

1. Measure the concentricity of the valve seat using a dial indicator. Total runout should not exceed 0.050 mm (0.002 inch.) total indicator reading.

   NOTE: Valve seats which are worn or burned can be reworked, provided that the correct angle and seat width are maintained. Otherwise the cylinder head must be replaced.

2. Check the sealing of the valve(s) to the valve seat(s) on the cylinder head(s):
   - Coat the valve seat (3) **LIGHTLY** with Prussian blue.
   - Install the valve into the cylinder head.
   - Rotate the valve onto the valve seat using light pressure.
   - Using care not to wipe the Prussian blue. Remove the valve from the cylinder head.
   - If the blue is transferred to the center of the valve face (4), contact is within specifications.
   - If the blue is transferred to the top edge of the valve face, then lower the valve seat with a 15 degree stone.
   - If the blue is transferred to the bottom edge of the valve face, then raise the valve seat with a 65

degree stone.

3. When the seat is properly positioned. The width of the intake seat should be 1.0 - 1.2 mm (0.04 - 0.05 in.) and the exhaust seats should be 1.41 - 1.61 mm (0.055 - 0.063 in.).

VALVE AND SPRING INSTALLED HEIGHT

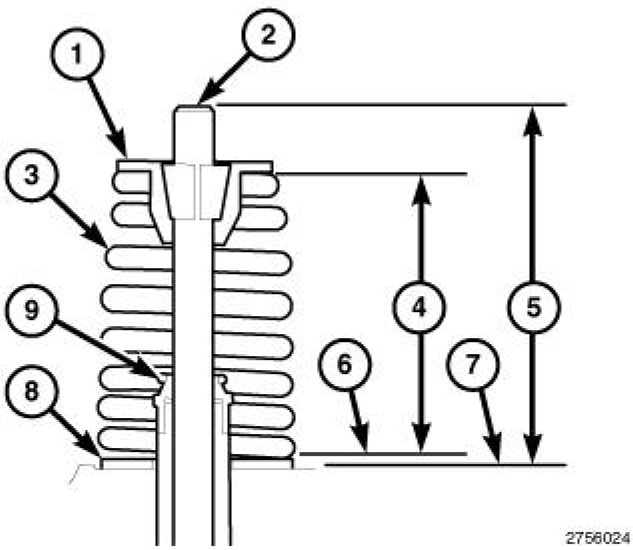

Fig. 324: Checking Valve Spring Installed Height
Courtesy of CHRYSLER GROUP, LLC

NOTE: **If the valves are being reused, reassemble them into their original locations.**

1. Coat the valve stems (2) with clean engine oil and install the valves onto the cylinder head.
2. If the valves or valve seats have been refinished, check the valve tip height (5). If the valve tip height (5) exceeds the specification, grind the valve tip until it is within specification. Refer to **ENGINE SPECIFICATIONS**. Make sure the measurement is taken from the cylinder head surface (7) to the top of the valve stem (2).

   NOTE: **Make sure that the garter spring is intact around the top of the valve guide seal.**

3. If removed, install the spring seat and valve guide seal over the valve guide. Refer to **SEAL(S), VALVE GUIDE, INSTALLATION**.

NOTE: **Number 3 cylinder intake valve spring compression shown in illustration, all other valves similar.**

5. Compress the valve spring (3) with the Valve Spring Compressor Adapter (special tool #10224, Adapter, Valve Spring) (2) mounted in the Valve Spring Compressor (special tool #C-3422-D, Compressor, Valve Spring) (1). Install the retaining locks (4) and release the valve spring compressor.

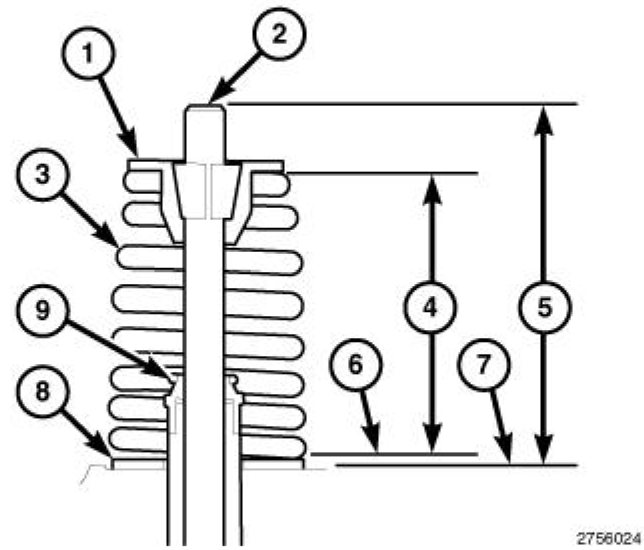

Fig. 327: Checking Valve Spring Installed Height

6. If the valves or valve seats have been refinished and the installed valve spring height (4) is greater than 40.0 mm (1.575 in.). Install a second spring seat (8) in the head counter bore under the original valve spring seat to bring the spring height within specification. Make sure the measurement is taken from the top of spring seat (6) to the bottom surface of spring retainer (1).

REMOVAL

REMOVAL

1. Remove the cylinder head(s). Refer to **CYLINDER HEAD, REMOVAL**.

NOTE: **If the springs are to be reused, identify their positions so that they can be reassembled into their original locations.**

2. Remove the valve spring(s). Refer to **SPRING(S), VALVE, REMOVAL**.

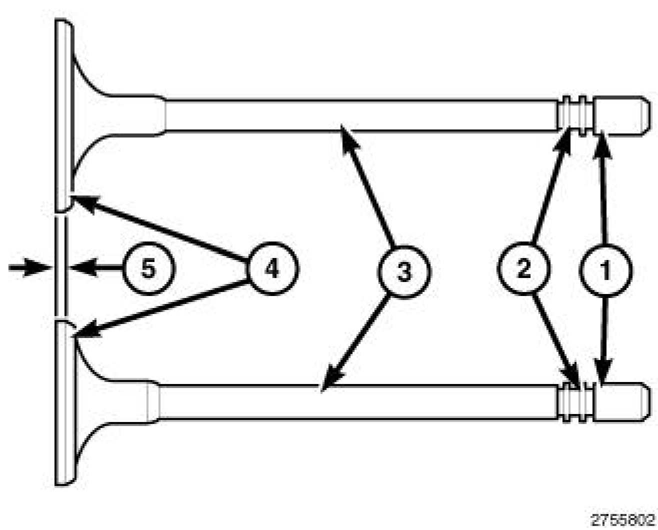

Fig. 328: Inspecting Valve Margin

Courtesy of CHRYSLER GROUP, LLC

CAUTION: Before removing the valves, remove any burrs from the valve stem retainer lock grooves (2) and stem tip (1) to prevent damage to the valve guides.

3. Remove the valve(s) (3). Identify each valve to ensure installation in the original location.
4. If required, remove the valve guide seal and spring seat. Refer to **SEAL(S), VALVE GUIDE, REMOVAL**.

INSPECTION

INSPECTION

VALVES

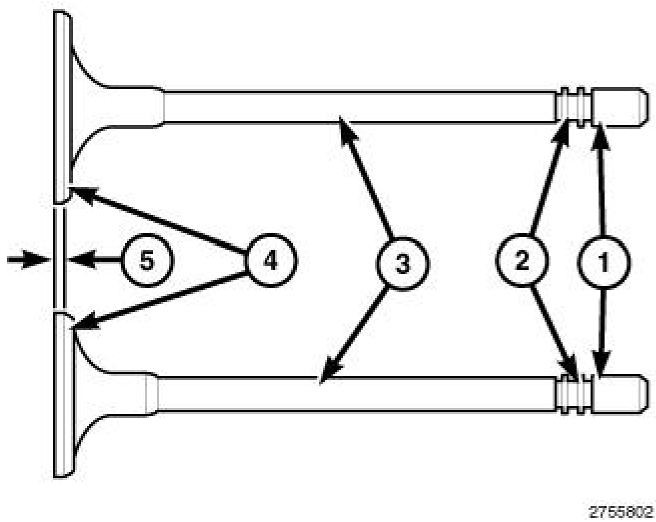

Fig. 329: Inspecting Valve Margin

1. Clean and inspect the valves thoroughly. Replace burned, warped and cracked valves.
2. Inspect the retainer lock grooves for wear or damage (2).
3. Inspect the valve face (4) for wear and pitting.
4. Measure the valve stems (3) and margins (5) for wear. Refer to **ENGINE SPECIFICATIONS**.

VALVE GUIDES

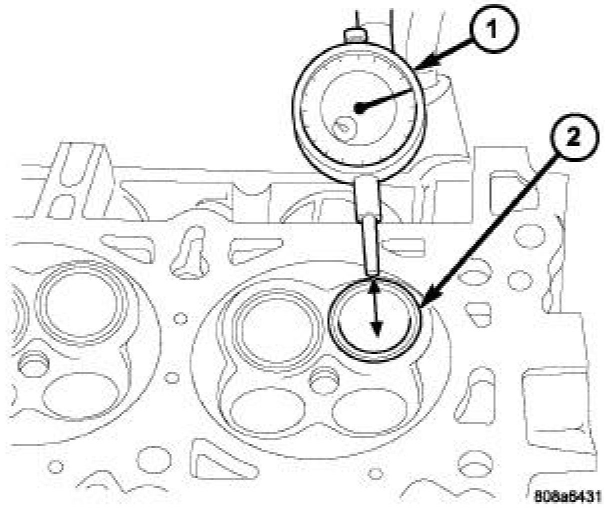

Fig. 330: Measuring Valve Guide Wear - Typical
Courtesy of CHRYSLER GROUP, LLC

1. Remove carbon and varnish deposits from inside of the valve guides with a reliable guide cleaner.
2. Measure valve stem-to-guide clearance as follows:
3. Install the valve (2) into the cylinder head so that it is 15 mm (0.590 inch.) off of the valve seat. A small piece of hose may be used to hold the valve in place.
4. Attach the Dial Indicator Set (special tool #C-3339A, Set, Dial Indicator) (1) to the cylinder head and set it at a right angle to the valve stem being measured.

NOTE: **If stem-to-guide clearance exceeds specifications, you must measure the valve stem. If the valve stem is within specification or if the valve guide is loose in the cylinder head, replace the cylinder head.**

5. Move the valve to and from the indicator. Compare this reading to the specification. Refer to ENGINE SPECIFICATIONS.

INSTALLATION

INSTALLATION

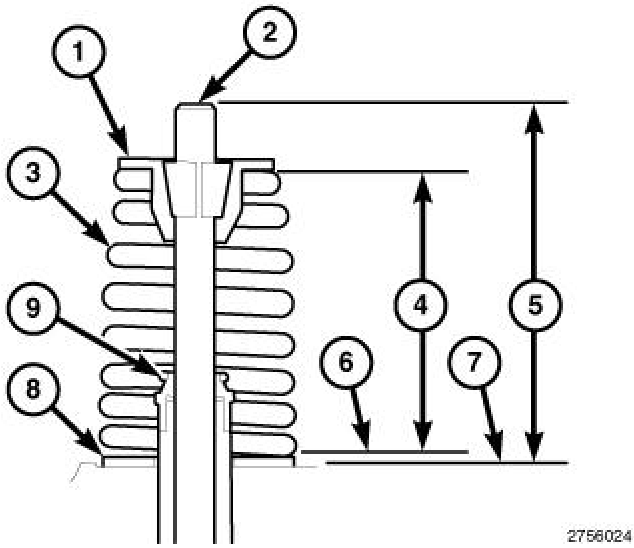

Fig. 331: Checking Valve Spring Installed Height

1. Coat the valve stems (2) with clean engine oil and install the valves into the cylinder head.

NOTE: **If the valves are being reused, reassemble them into their original locations.**

2. If the valves or valve seats have been refinished, check the valve tip height (5). If the valve tip height (5) exceeds the specification, grind the valve tip until it is within specification. Refer to **ENGINE SPECIFICATIONS**. Make sure the measurement is taken from the cylinder head surface (7) to the top of the valve stem (2).
3. If removed, install the spring seat and valve guide seal over the valve guide. Refer to **SEAL(S), VALVE GUIDE, INSTALLATION**.

NOTE: **Reassemble the valves springs into their original locations. If the valves or valve seats have been refinished, verify that the valve spring installed height is within specification. Refer to ENGINE SPECIFICATIONS.**

4. Install the valve spring(s). Refer to **SPRING(S), VALVE, INSTALLATION**.
5. Install the cylinder head(s). Refer to **CYLINDER HEAD, INSTALLATION**.

ENGINE BLOCK

DESCRIPTION

DESCRIPTION

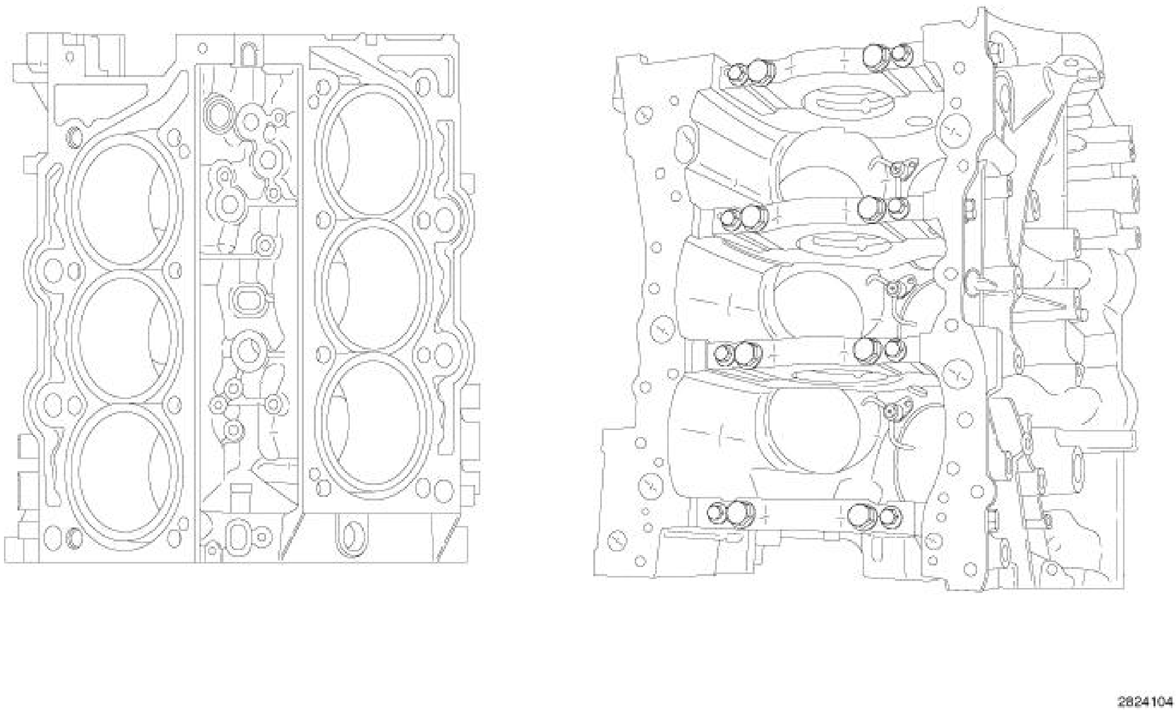

Fig. 332: Cylinder Block & Main Bearing Caps
Courtesy of CHRYSLER GROUP, LLC

The cylinder block is a 60 degree high-pressure die cast aluminum design with cast steel cylinder liners.

- The leading side of the block is on the right side and houses cylinders 1, 3 and 5.
- The cylinder block is an open deck design with cut slots between each cylinder.
- Two knock sensors are located in the block valley.
- The cylinder block has three sets of piston cooling jets which are attached to the main oil gallery.
- The four powdered metal main bearing caps are a cross-bolted design and have directional arrows molded into the caps.
- The number 2 main bearing is the location for the two piece upper half thrust bearings.
- The thrust bearings are installed with the oil groves facing outward.
- The main bearing caps are a six bolt design and cross-bolted for improved lower end strength.
- There are three oil drain back drillings located on each of the cylinder banks.

STANDARD PROCEDURE

MEASURING BEARING CLEARANCE USING PLASTIGAGE

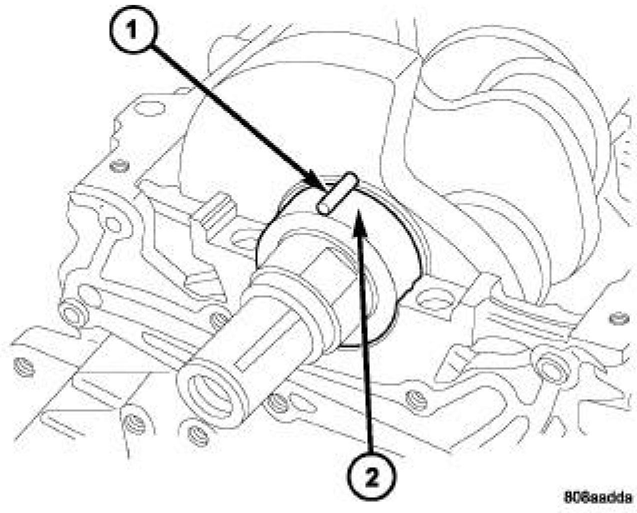

Fig. 333: Plastigage Placed In Lower Shell-Typical
Courtesy of CHRYSLER GROUP, LLC

NOTE: **Typical crankshaft journal shown in illustration.**

Engine crankshaft and connecting rod bearing clearances can be determined by the use of Plastigage or equivalent. The following is the recommended procedure for the use of Plastigage:

1. Remove the oil film from surface to be checked. Plastigage is soluble in oil.
2. Place a piece of Plastigage (1) across the entire width of the journal (In addition, suspected areas can be checked by placing the Plastigage in the suspected area). Plastigage must not crumble in use. If brittle, obtain fresh stock.

   NOTE: **DO NOT rotate the crankshaft. Plastigage will smear, causing inaccurate results.**

3. Torque the bearing cap bolts of the bearing being checked to the proper specification. Refer to **TORQUE SPECIFICATIONS**.

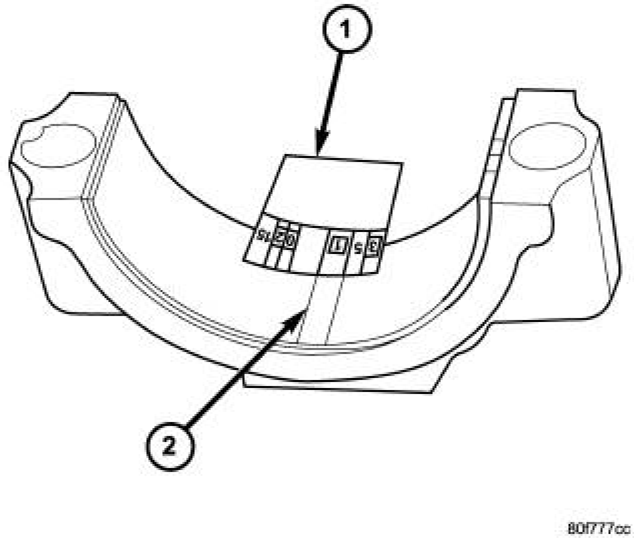

Fig. 334: Measuring Bearing Clearance With Plastigage
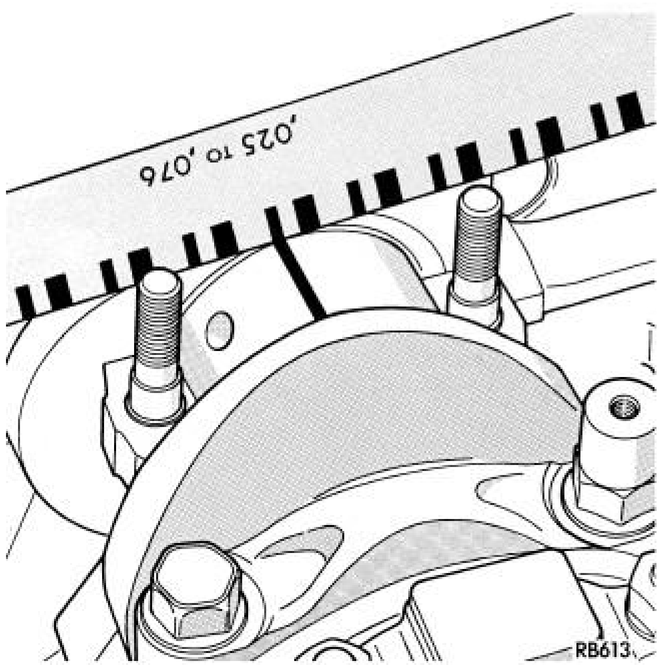
Courtesy of CHRYSLER GROUP, LLC

NOTE: **Typical connecting rod cap shown in illustration.**

4. Remove the bearing cap and compare the width of the flattened Plastigage (2) with the scale provided on the package (1). Locate the band closest to the same width. This band shows the amount of clearance. Differences in readings between the ends indicate the amount of taper present or the possibility of foreign material trapped under the bearing insert.
5. Record all readings taken. Compare clearance measurements to specification. Refer to **ENGINE SPECIFICATIONS**.



[Fig. 335: Checking Connecting Rod Bearing Clearance-Typical]
Courtesy of CHRYSLER GROUP, LLC

NOTE: **Typical connecting rod journal shown in illustration.**

NOTE: **Plastigage is available in a variety of clearance ranges. Use the most appropriate range for the specifications you are checking. Plastigage generally is accompanied by two scales. One scale is in inches, the other is a metric scale.**

6. Install the proper bearings to achieve the specified bearing clearances.
7. Repeat the Plastigage measurement to verify your bearing selection prior to final assembly.

CYLINDER BORE DEGLAZING

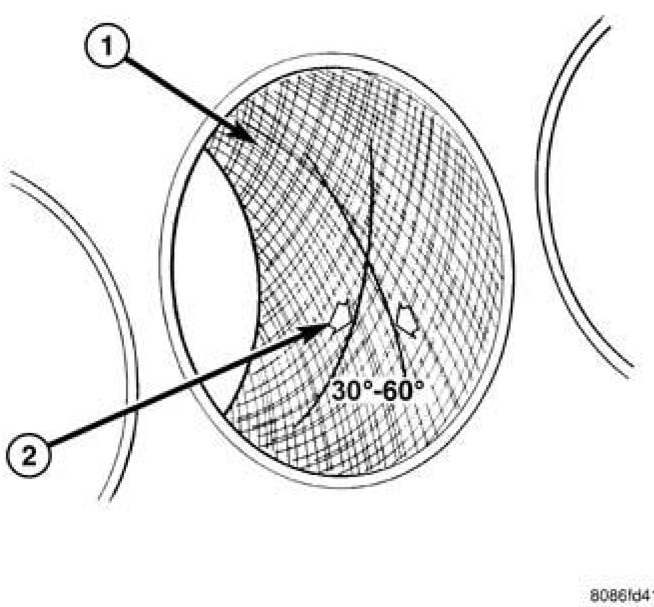
Before deglazing, mask the crankcase area to keep abrasive materials from entering the engine lower end. Tape off any openings to prevent abrasive material from entering the coolant and oil circuits.

CAUTION: **DO NOT use rigid type hones to remove cylinder wall glaze.**

1. Select an appropriate size flexible ball hone.

CAUTION: **DO NOT use engine or transmission oil, mineral spirits, or kerosene.**

2. Deglazing of the cylinder walls may be done if the cylinder bore is straight and round. About 20-60 strokes, depending on the condition of the cylinder bore, will be sufficient to provide a satisfactory surface. Use a light **honing** oil, available from major oil distributors.



[Fig. 336: Identifying Cylinder Bore Crosshatch Pattern]
Courtesy of CHRYSLER GROUP, LLC

3. Deglazing should be done by moving the hone up and down fast enough to get a crosshatch pattern. The hone marks should intersect at 30Â° to 60Â° inclusive angle for proper seating of rings.
4. A controlled hone motor speed between 200 and 300 RPM is necessary to obtain the proper crosshatch angle (1). The number of up and down strokes per minute can be regulated to get the desired 30Â° to 60Â° inclusive angle (2). Faster up and down strokes increase the crosshatch angle.
5. After deglazing, it is necessary that the block be cleaned to remove all traces of abrasive. Use a brush to wash parts with a solution of hot water and detergent. Dry parts thoroughly. Use a clean, white, lint-free cloth to check that the bore is clean. Oil the bores after cleaning to prevent rusting. Upon completion, perform a visual inspection of the cylinder block passages to inspect for abrasive debris. If any debris is found, repeat the cleaning process.

NOTE: **Cylinder bore diameter should not increase more than 20 microns during deglazing process from original nominal bore diameter, if the maximum of 20 microns is exceeded, the cylinder block must be replaced. If deglazing the cylinder bore cannot remove the light scratches and scuffs the cylinder block should be replaced.**

INSPECTION

INSPECTION

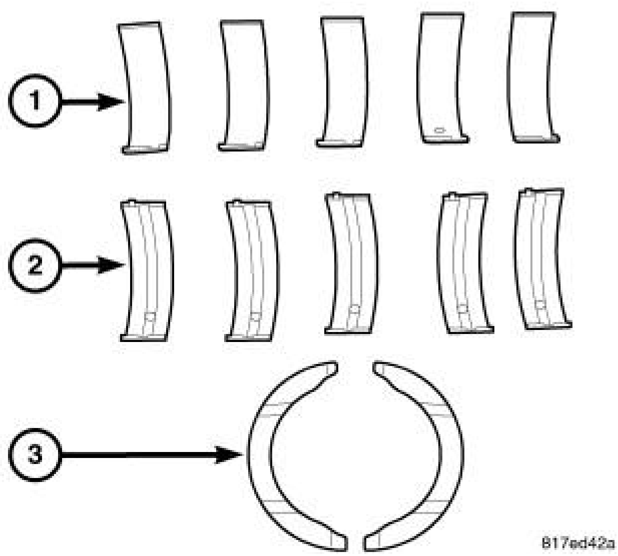


Fig. 337: Bearing Identification
Courtesy of CHRYSLER GROUP, LLC

1. Wipe the bearing inserts (1, 2) clean.
   - Inspect the inserts for abnormal wear patterns, scoring, grooving, fatigue, pitting and for metal or other foreign material imbedded in the lining.
   - Inspect the back of the inserts for fractures, scrapes, or irregular wear patterns.
   - Inspect the insert locking tabs for damage.
   - Inspect the crankshaft thrust bearings (3) for scoring, scratches, wear or blueing.
2. Replace any bearing that shows abnormal wear. Refer to STANDARD PROCEDURE.
3. Inspect the main bearing bores for signs of scoring, nicks and burrs.

4. If the cylinder block main bearing bores show damage the engine block must be replaced.

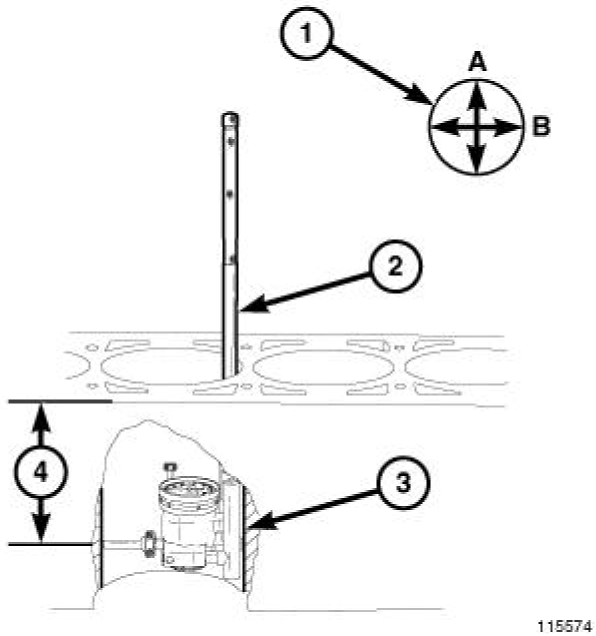

Fig. 338: Measuring Cylinder Bore Diameter
Courtesy of CHRYSLER GROUP, LLC

5. Use the Cylinder Indicator (special tool #C-119, Cylinder Indicator) (2) to correctly measure the inside diameter of the cylinder bore (3). A cylinder bore gauge capable of reading in 0.003 mm (0.0001 in.) INCREMENTS is required. If a bore gauge is not available, do not use an inside micrometer.
6. Measure the inside diameter of the cylinder bore at three levels below the top of the bore (4). Start at the top of the bore, perpendicular (across or at 90 degrees) to the axis of the crankshaft at point A (1).
7. Repeat the measurement near the middle of the bore, then repeat the measurement near the bottom of the bore.
8. Determine taper by subtracting the smaller diameter from the larger diameter.
9. Rotate the Cylinder Indicator 90Â° to point B (1) and repeat the three measurements. Verify that the maximum taper is within specification. Refer to **ENGINE SPECIFICATIONS**.
10. Determine out-of-roundness by comparing the difference between A and B at each of the three levels. Verify that the maximum out of round is within specification. Refer to **ENGINE SPECIFICATIONS**.

NOTE: **A slight amount of taper always exists in the cylinder bore after the engine has been in use for a period of time.**

11. If cylinder bore taper and out-of-roundness are within specification, the cylinder bore can be honed. Refer to **ENGINE BLOCK, STANDARD PROCEDURE**. If the cylinder bore taper or out-of-round condition exceeds the maximum limits, the cylinder block must be replaced.

BEARING(S), CONNECTING ROD

STANDARD PROCEDURE

CONNECTING ROD BEARING FITTING

Bearing oil clearance can also be determined by using Plastigage or equivalent. Refer to **ENGINE BLOCK,**

STANDARD PROCEDURE.

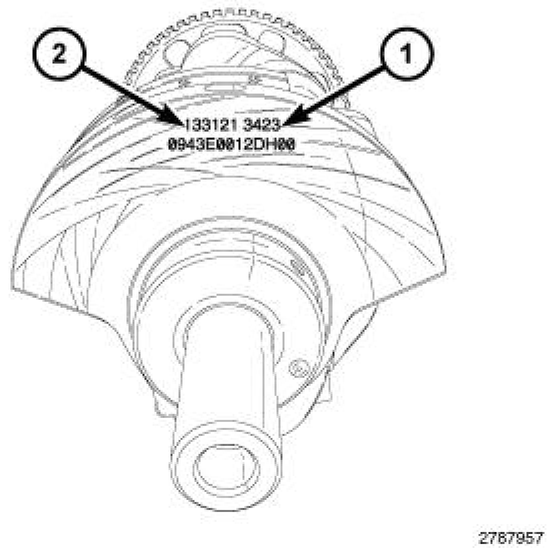

Fig. 339: Crankshaft Main Bearing Journal Diameter Grade Markings & Connecting Rod Bearing Journal Diameter Grade Markings

The connecting rod bearings are "select fit" to achieve proper oil clearance. Connecting rod bearing journal diameter grade markings (2) are stamped into the front crankshaft counterweight. These marks are read from left to right, corresponding with journal number 1, 2, 3, 4, 5, 6. Select the bearing size that corresponds to the crankshaft markings for each rod bearing journal.

Connecting rod bearing journal diameter grade markings correspond to specific journal diameters. The chart below identifies the three crankshaft grade markings and their associated journal diameters.

Crankshaft Marking	Journal Size mm (in.)
1	58.9910 - 58.9969 mm (2.3225 - 2.3227 in.)
2	58.9970 - 59.0029 mm (2.3227 - 2.3229 in.)
3	59.0030 - 59.0090 mm (2.3229 - 2.3232 in.)

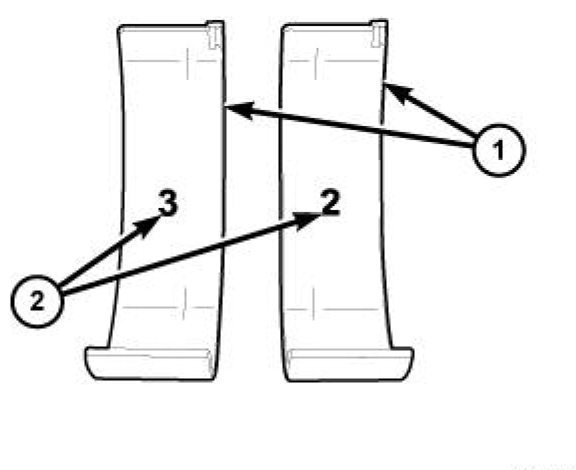

Fig. 340: Connecting Rod Bearing Shells & Bearing Size

NOTE: **Install the rod bearings in pairs. Do not mix sizes or use a new bearing half with an old bearing half.**

The connecting rod bearing shells (1) are marked with the bearing size (2) on the bearing lining surface. The bearings are available in three different sizes in order to achieve the desired oil clearance.

Rod bearing shells are available in three sizes. The chart below identifies the three bearing sizes.

Bearing Marking	Size mm (in.)
1	1.583 - 1.580 mm (0.0623 - 0.0622 in.)
2	1.580 - 1.577 mm (0.0622 - 0.0621 in.)
3	1.577 - 1.574 mm (0.0621 - 0.0620 in.)

CONNECTING ROD BEARING REPLACEMENT

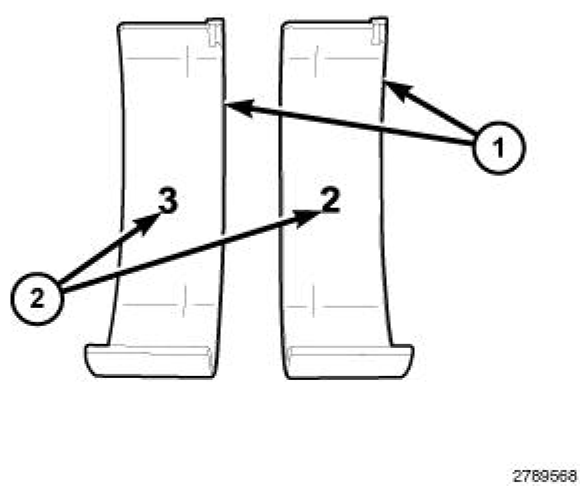

Fig. 341: Connecting Rod Bearing Shells & Bearing Size
Courtesy of CHRYSLER GROUP, LLC

The connecting rod bearings (1) can be serviced in-vehicle. They must be replaced one-at-a-time in order to prevent the pistons from contacting the valves. The connecting rod bearings are "select fit" to achieve proper oil clearances. Refer to **BEARING(S), CONNECTING ROD, STANDARD PROCEDURE**.

1. Disconnect and isolate the negative battery cable.
2. Remove the spark plugs. Refer to **SPARK PLUG, REMOVAL** .
3. Remove the oil pan, oil pump pick-up and engine oil pump. Refer to **PUMP, ENGINE OIL, REMOVAL**.

CAUTION:	**DO NOT use a number stamp or a punch to mark connecting rods or caps, as damage to connecting rods could occur**

NOTE:	**Connecting rods and bearing caps are not interchangeable and should be marked before removing to ensure correct reassembly.**

5. Mark connecting rod and bearing cap positions (1) using a permanent ink marker or scribe tool.

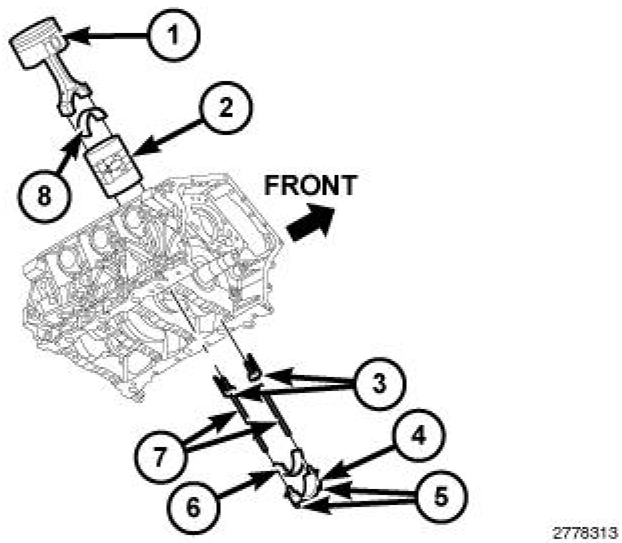

Fig. 344: Piston, Connecting Rod Cap, Bolts, Plastic Guide Plates & Guide Pins
Courtesy of CHRYSLER GROUP, LLC

NOTE:	**Typical V6 engine configuration shown in illustration.**
CAUTION:	**Replace only one connecting rod bearing at a time while all other connecting rod bearing caps remain properly tightened. If all connecting rod bearing caps are removed, crankshaft rotation will result in valve and/or piston damage.**
CAUTION:	**Care must be taken not to damage the fractured rod and cap joint face surfaces, as engine damage may occur.**

6. Remove the connecting rod cap bolts (5) and the connecting rod cap (4). Discard the cap bolts.
7. Remove the plastic guide plates (3) from the Guide Pins (special tool #8189, Guide Pins) (7) and install the Guide Pins to the connecting rod being removed.

CAUTION:	**Care must be taken not to nick crankshaft journals, as engine damage may occur.**

8. Rotate the crankshaft away from the connecting rod and remove the bearing shell.
9. Inspect the rods and bearings for abnormal wear patterns, scoring, grooving, fatigue, pitting and for metal or other foreign material imbedded in the lining. Refer to **INSPECTION**.
10. If required, check the connecting rod bearing clearances by the use of Plastigage or equivalent. Refer to **ENGINE BLOCK, STANDARD PROCEDURE**.
11. If required, select and fit new bearings to the connecting rod. Refer to **BEARING(S), CONNECTING ROD, STANDARD PROCEDURE**.
12. Install the bearing shell (8) on the connecting rod with the tang inserted into the machined groove in the rod. Lubricate the bearing surface with clean engine oil.
13. Rotate the crankshaft while guiding the connecting rod into position over the rod journal.

CAUTION: The connecting rod bolts must not be reused. Always replace the connecting rod bolts whenever they are loosened or removed.

14. Install the bearing shell (6) on the connecting rod cap (4) with the tang inserted into the machined groove in the cap. Lubricate the bearing surface with clean engine oil.

NOTE: Do not lubricate the threads of the connecting rod cap bolts (5).

15. Install the connecting rod cap and bearing with the tang on the same side as the rod. Tighten the **NEW** connecting rod cap bolts (5) to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
16. If required, check the connecting rod side clearance. Refer to **STANDARD PROCEDURE**.
17. Repeat the previous steps for each connecting rod bearing being replaced.

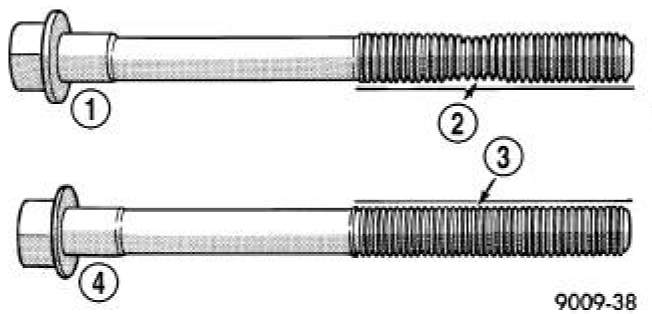

Fig. 345: Checking Cylinder Head Bolts For Stretching (Necking)
Courtesy of CHRYSLER GROUP, LLC

CAUTION: The main bearing cap bolts are tightened using a torque plus angle procedure. The bolts must be examined BEFORE reuse. If the threads are necked down the bolts must be replaced.

18. Check the main bearing cap bolts for necking by holding a scale or straight edge against the threads. If all the threads do not contact the scale (2) the bolt must be replaced.

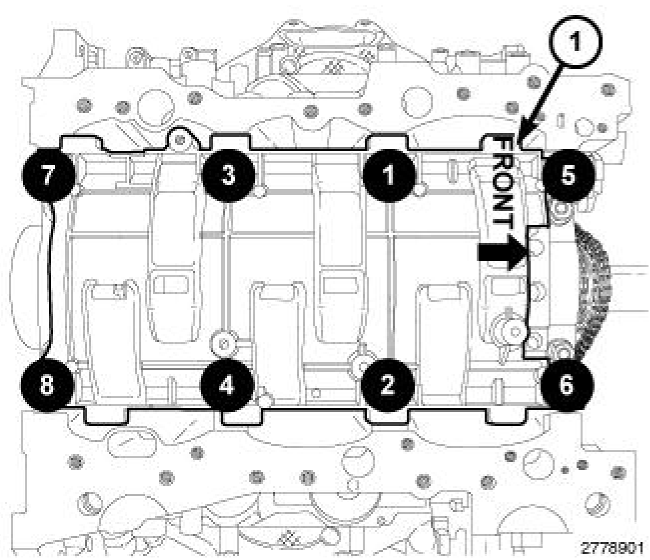

Fig. 346: Windage Tray With Main Bearing Cap Bolts Installation Sequence

19. Install the windage tray with eight main bearing cap bolts. Tighten the bolts in the sequence shown in illustration to 21 N.m (16 ft. lbs.) plus an additional 90Â° turn.
20. Install the engine oil pump, oil pump pick-up and oil pan. Refer to **PUMP, ENGINE OIL, INSTALLATION**.
21. Install the spark plugs and ignition coils. Refer to **SPARK PLUG, INSTALLATION** .
22. If removed, install the oil filter and fill the engine crankcase with the proper oil to the correct level. Refer to **STANDARD PROCEDURE**.
23. Connect the negative battery cable.
24. Operate the engine until it reaches normal operating temperature.

The upper main bearing shell (2) and lower main bearing shell (1) are marked with the bearing size (3) on the bearing lining surface. The upper and lower bearings are available in five different sizes and can be mixed on a journal in order to achieve the proper oil clearance.

Upper and lower main bearing shells are available in five sizes. The chart below identifies the five bearing sizes.

Bearing Marking	Size mm (in.)
1	2.4951 - 2.4987 mm (0.0982 - 0.0984 in.)
2	2.4915 - 2.4951 mm (0.0981 - 0.0982 in.)
3	2.4879 - 2.4915 mm (0.0979 - 0.0981 in.)
4	2.4843 - 2.4879 mm (0.0978 - 0.0979 in.)
5	2.4807 - 2.4843 mm (0.0977 - 0.0978 in.)

MAIN BEARING REPLACEMENT

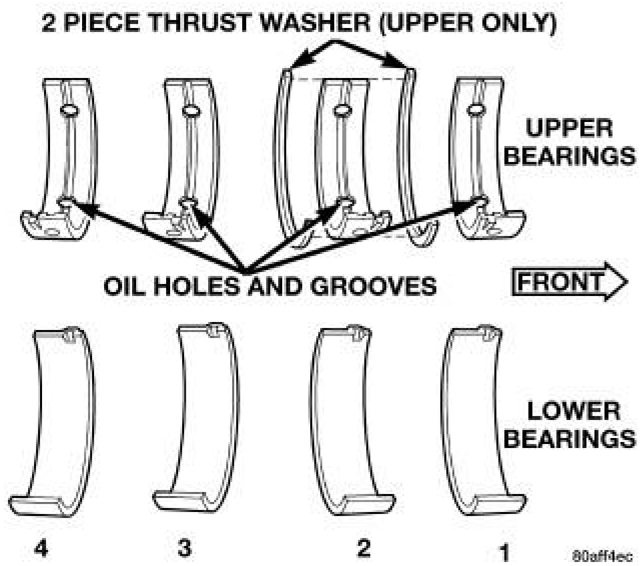

Fig. 350: Main Bearing Identification
Courtesy of CHRYSLER GROUP, LLC

The main bearings are serviced in-vehicle. They must be replaced one-at-a-time in order to properly support the crankshaft. The upper and lower main bearing shells are NOT interchangeable. The upper and lower main bearings are "select fit" to achieve proper oil clearances. Refer to **STANDARD PROCEDURE**.

1. Disconnect and isolate the negative battery cable.

4. Remove the eight main bearing tie bolts in the sequence shown in illustration.

CAUTION: **DO NOT use a number stamp or a punch to mark main bearing caps, as damage to main bearings could occur.**

NOTE: **Main bearing caps are not interchangeable and are marked to insure correct assembly.**

5. Mark the main bearing cap positions using a permanent ink marker or a scribe tool.

NOTE: **Typical V6 engine configuration shown in illustration.**

CAUTION: **Replace only one main bearing at a time while all other main bearing caps remain properly tightened. If all main bearing caps are removed, the weight of the unsupported crankshaft will damage the crankshaft oil seals.**

NOTE: **Replace the main bearings in the following order; 2, 3, 1, 4.**

6. Remove the two cap bolts (2) and remove the main bearing cap (1).
7. When removing the No. 2 bearing cap, also remove the thrust washers (5).
8. Slide the upper main bearing half (6) out from between the crankshaft and the engine block.
9. If required, select fit new main bearings to the engine block. Refer to **STANDARD PROCEDURE**.
10. Lubricate the upper main bearing half (6) with clean engine oil and slide the bearing into position.

NOTE: **Typical V6 engine configuration shown in illustration.**

11. When installing thrust washers (1) at the No. 2 main bearing location, use the following procedure:
    a. Move the crankshaft forward to the limit of travel. Lubricate and install the front thrust washer (1) by rolling the washer onto the machined shelf between the No. 2 upper main bulk head and crankshaft thrust surface.
    b. Move the crankshaft rearward to the limit of travel. Lubricate and install the rear thrust washer by rolling the washer onto the machined shelf between the No. 2 upper main bulk head and crankshaft thrust surface.

13. Lubricate and install the lower bearing half (3) onto the main cap (1).
14. Install the main bearing cap (1) with two inner main bearing cap bolts (2) tightened to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
15. Repeat the previous steps for main bearings 3, 1 and 4.
16. Measure crankshaft end play. Refer to **CRANKSHAFT, STANDARD PROCEDURE**.

18. Install the eight main bearing tie bolts. Tighten bolts in the sequence shown in illustration to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
19. Install the engine oil pump. Refer to **PUMP, ENGINE OIL, INSTALLATION**.
20. If removed, install the accessory drive belt. Refer to **BELT, SERPENTINE, INSTALLATION** .
21. Install the spark plugs. Refer to **SPARK PLUG, INSTALLATION** .
22. If removed, install the oil filter and fill the engine crankcase with the proper oil to the correct level. Refer to **STANDARD PROCEDURE**.

23. Connect the negative battery cable.
24. Operate the engine until it reaches normal operating temperature.

CRANKSHAFT

DESCRIPTION

DESCRIPTION

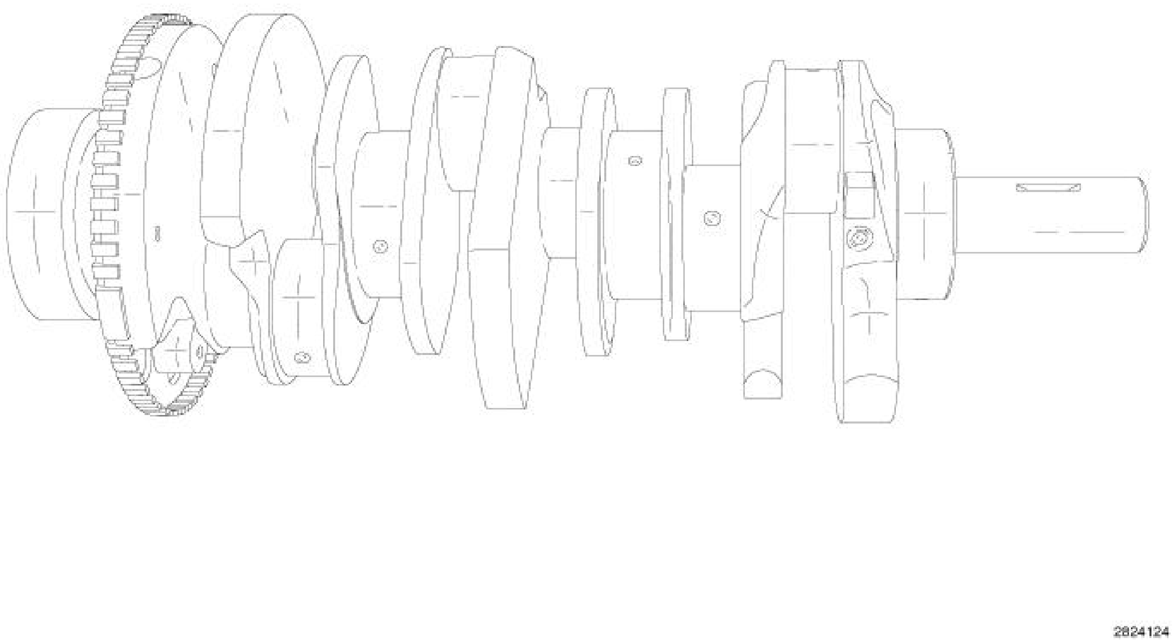

Fig. 359: Crankshaft
Courtesy of CHRYSLER GROUP, LLC

The crankshaft is a cast design and is constructed using ductile iron. The crankshaft is a three throw split pin design with counterweights for balancing purposes. The main journals are crossed drilled for rod bearing lubrication. The crankshaft is supported by four select fit main bearings with number 2 serving as the thrust washer location. The rear counterweight has provisions for crankshaft position sensor target wheel mounting. Both the front and rear seals are a single piece design and are mounted to the timing cover and cylinder block.

STANDARD PROCEDURE

STANDARD PROCEDURE - END PLAY

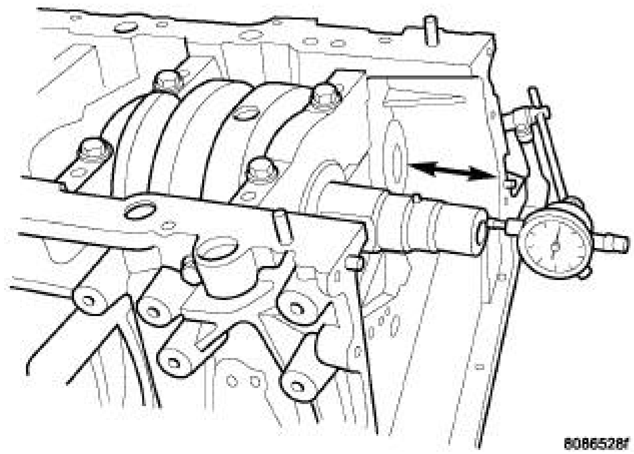

Fig. 360: Checking Crankshaft End Play
Courtesy of CHRYSLER GROUP, LLC

NOTE: **Typical V6 engine shown in illustration.**

1. Mount Dial Indicator Set (special tool #C-3339A, Set, Dial Indicator) to a stationary point at the front of the engine. Locate the probe perpendicular against the nose of the crankshaft.
2. Move the crankshaft all the way to the rear of its travel.
3. Zero the dial indicator.
4. Move the crankshaft forward to the limit of travel and read the dial indicator. Compare the measured end play to the specification. Refer to **ENGINE SPECIFICATIONS**.

NOTE: **Crankshaft thrust washers are not selectable and are only available in a single thickness.**

REMOVAL

REMOVAL

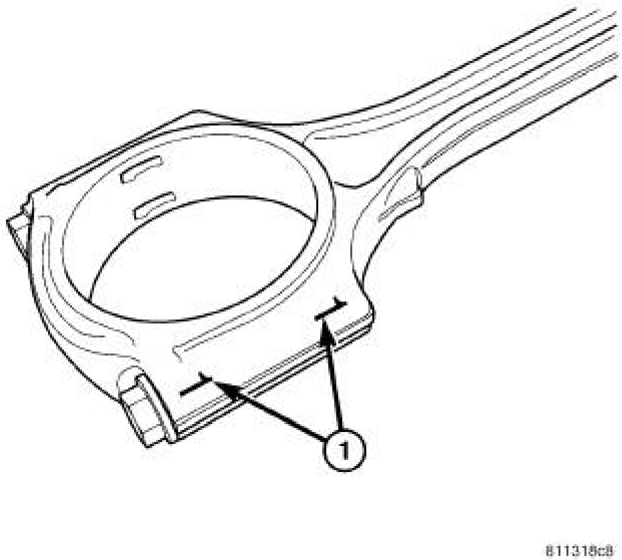
2. Remove the cylinder head covers, spark plugs, upper oil pan, engine timing cover, timing chain and sprockets. Refer to **CHAIN AND SPROCKETS, TIMING, REMOVAL**.
3. Remove the flexplate and the rear crankshaft oil seal. Refer to **SEAL, CRANKSHAFT OIL, REAR, REMOVAL**.
4. Remove the oil pump pick-up and engine oil pump. Refer to **PUMP, ENGINE OIL, REMOVAL**.
5. Remove the eight main bearing cap bolts from the windage tray in the sequence shown in illustration and remove the windage tray (1).



[Fig. 363: Connecting Rod To Cylinder Identification]

CAUTION: **DO NOT use a number stamp or a punch to mark connecting rods or caps, as damage to connecting rods could occur**

NOTE: **Connecting rods and bearing caps are not interchangeable and should be marked before removing to ensure correct reassembly.**

6. Mark connecting rod and bearing cap positions (1) using a permanent ink marker or scribe tool.

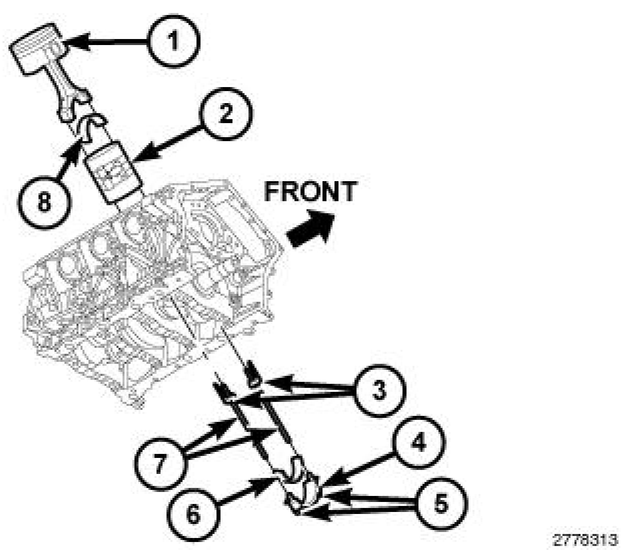

Fig. 364: Piston, Connecting Rod Cap, Bolts, Plastic Guide Plates & Guide Pins

NOTE: **Typical V6 engine configuration shown in illustration.**

CAUTION: Care must be taken not to damage the fractured rod and cap joint face surfaces, as engine damage may occur.

7. Remove the connecting rod cap bolts (5) and the connecting rod caps (4). Discard the cap bolts.

CAUTION: Care must be taken not to nick crankshaft journals, as engine damage may occur.

8. Remove the plastic guide plates (3) from the Guide Pins (special tool #8189, Guide Pins) (7) and install the Guide Pins to the connecting rod.

CAUTION: Avoid contact with the piston oil cooler jet(s). Positioning of the oil cooler jet(s) is critical for proper engine operation.

9. Push the connecting rod and piston into the cylinder until the connecting rod is clear of the crankshaft journal. Remove the guide pins. Repeat this procedure at each cylinder until all of the connecting rods are clear of the crankshaft.

CAUTION: **Do not rest the crankshaft on the target wheel (1). Damaged or bent target wheel teeth will destroy the target wheels ability to correctly relay crankshaft position to the crankshaft position sensor.**

12. Remove the crankshaft from the engine block.
13. If required, remove the four bolts (2) and the target wheel (1). Discard the four bolts.

INSPECTION

INSPECTION

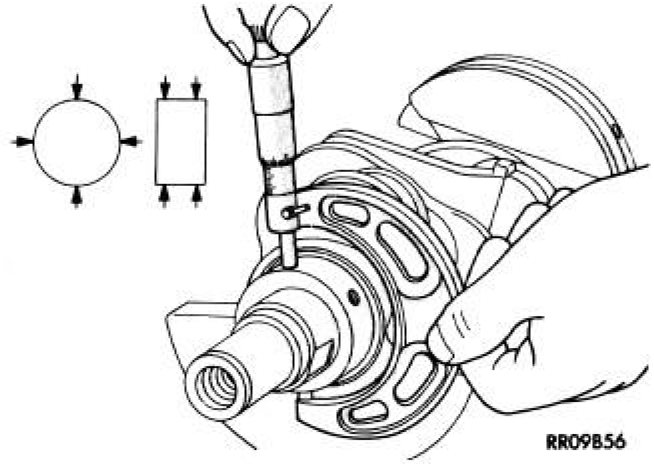

Fig. 368: Crankshaft Journal Measurements - Typical
Courtesy of CHRYSLER GROUP, LLC

NOTE: **Typical crankshaft journal measurements shown in illustration.**

1. Clean the oil off the bearing journals.
2. Determine the maximum diameter of the journals with a micrometer. Measure at two locations 90Ā° apart at each end of the journals.
3. Compare the measured rod journal diameter to the crankshaft connecting rod bearing journal diameter grade marking chart. Refer to **BEARING(S), CONNECTING ROD, STANDARD PROCEDURE**. Select the bearing size that corresponds to the crankshaft markings for each rod bearing journal that will provide the proper oil clearance.
4. Compare the measured main bearing journal diameter to the crankshaft main bearing journal diameter grade marking chart. Refer to **STANDARD PROCEDURE**. Obtain the main bearing journal grade identification marks from the engine block and select the upper and lower main bearing sizes that will provide the proper oil clearance.
5. For connecting rod journals, verify that the maximum taper and maximum out of round are within specifications. Refer to **ENGINE SPECIFICATIONS**.
6. For main bearing journals, verify that the maximum taper and maximum out of round are within specifications. Refer to **ENGINE SPECIFICATIONS**.

12. If removed, install the bearing shell (8) on the connecting rod with the tang inserted into the machined groove in the rod. Lubricate the bearing surface with clean engine oil.

CAUTION: **Care must be taken not to nick crankshaft journals, as engine damage may occur.**

13. Remove the plastic guide plates (3) from the Guide Pins (special tool #8189, Guide Pins) (7) and install the Guide Pins to the connecting rod.

CAUTION: **Avoid contact with the piston oil cooler jet(s). Positioning of the oil cooler jet(s) is critical for proper engine operation.**

14. Pull the connecting rod and piston toward the crankshaft until the connecting rod is seated on the crankshaft journal. Remove the guide pins.

CAUTION: **The connecting rod bolts must not be reused. Always replace the connecting rod bolts whenever they are loosened or removed.**

15. If removed, install the bearing shell (6) on the connecting rod cap (4) with the tang inserted into the machined groove in the cap. Lubricate the bearing surface with clean engine oil.

NOTE: **Do not lubricate the threads of the connecting rod cap bolts (5).**

16. Install the connecting rod cap and bearing with the tang on the same side as the rod. Tighten the **NEW** connecting rod cap bolts (5) to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
17. If required, check the connecting rod side clearance. Refer to **STANDARD PROCEDURE**.
18. Repeat the previous steps for the remaining connecting rods.

RING(S), PISTON

STANDARD PROCEDURE

STANDARD PROCEDURE - PISTON RING FITTING

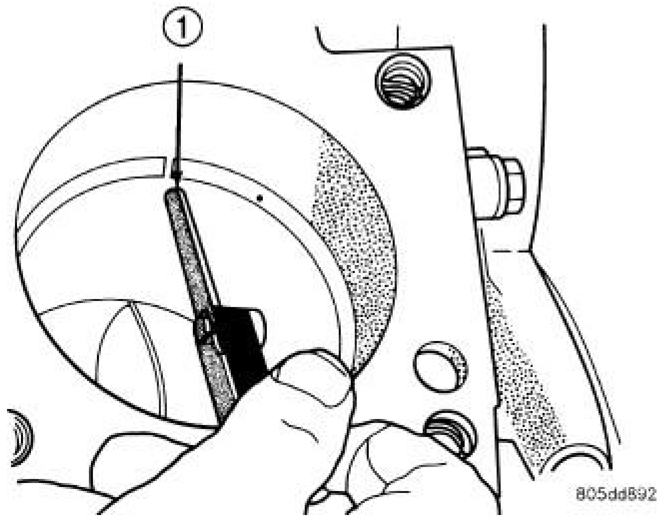

Fig. 385: Measuring Piston Ring End Gap
Courtesy of CHRYSLER GROUP, LLC

1. Wipe the cylinder bore clean.
2. Using a piston, to ensure that the ring is squared in the cylinder bore, slide the ring downward into the cylinder to a position 12 mm (0.50 in.) from the bottom of the cylinder bore.
3. Using a feeler gauge (1), check the ring end gap. Replace any rings not within specification.

Ring Position	Ring End Gap
No. 1 (top) Ring	0.25 - 0.40 mm (0.010 - 0.016 in.)
No. 2 (center) Ring	0.30 - 0.45 mm (0.012 - 0.018 in.)
Oil Control Ring (Steel Rail)	0.15 - 0.66 mm (0.006- 0.26 in.)

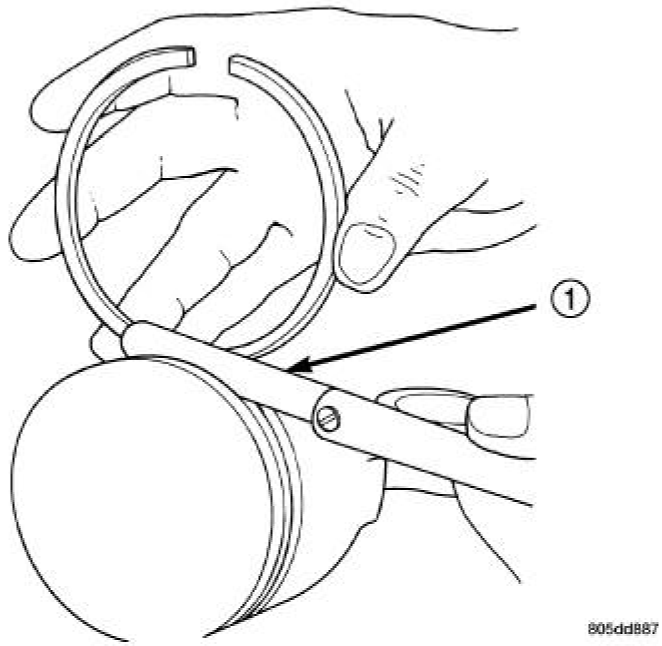

Fig. 386: Checking Piston Ring Grooves Clearances

4. Clean the piston ring grooves. Remove any nicks or burrs.
5. Measure the ring side clearance as shown in illustration. Make sure the feeler gauge (1) fits snugly between the ring land and the ring. Replace any ring not within specification.

Ring Position	Ring Side Clearance
No. 1 (top) Ring	0.025 - 0.033 mm (0.0010 - 0.0013 in.)
No. 2 (center) Ring	0.030 - 0.078 mm (0.0012 - 0.0031 in.)
Oil Control Ring (Steel Rails)	0.007 - 0.173 mm (.0003 - 0.0068 in.)

ROD, PISTON AND CONNECTING

DESCRIPTION

DESCRIPTION

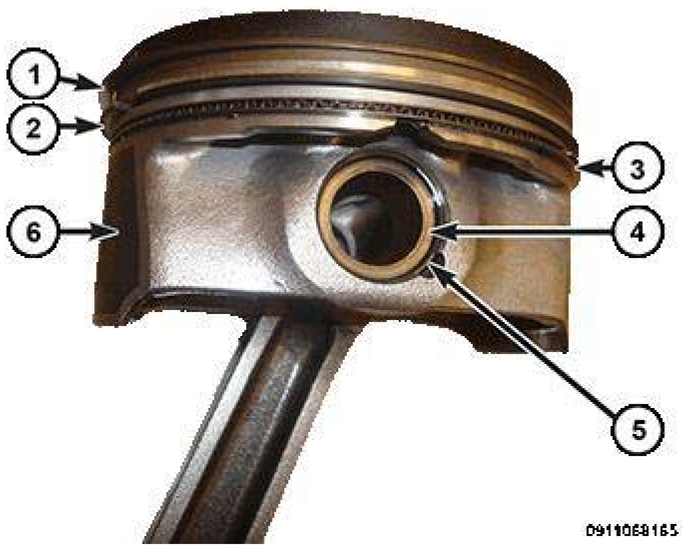

Fig. 395: Piston Components
Courtesy of CHRYSLER GROUP, LLC

CAUTION: Do not use a metal stamp to mark connecting rods as damage may result, instead use ink or a scratch awl.

The pistons are a lightweight design with ultra low tension piston rings for improved fuel economy:

- The pistons are made of a high strength aluminum alloy and the piston skirt (6) has a MolyTÃ® coating.
- The top piston ring land has an anodized coating for improved wear performance.
- The piston is connected to the rod using a full floating pin (5) with a locking clip (4) on both sides.
- The connecting rod is powder-forged steel with a bolted cracked cap design. The connecting rod bolts are not reusable.
- Pistons are available in three diameters (A, B and C) with grade markings for each bore indicated on the side of the cylinder block.
- The upper compression ring (1) is a 1.2 mm steel ring with Physical Vapor Deposition (PVD) coating.
- The intermediate compression ring (2) is 1.2 mm micro napier design.
- Both compression rings have a dot or a mark on the piston ring. The marked side of the ring must face the

top of the piston.

- The 2 mm three piece oil control ring (3) is very thin. Both the rail segments and the expander are nitride steel.

STANDARD PROCEDURE

PISTON FITTING

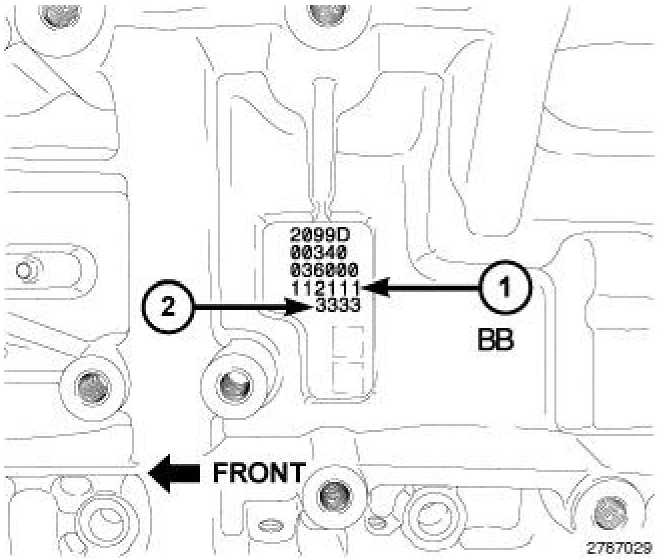

Fig. 396: Engine Block Main Bearing Journal Diameter Grade Markings
Courtesy of CHRYSLER GROUP, LLC

The pistons are "select fit" to achieve proper oil clearance. Engine block cylinder bore diameter grade markings (1) are stamped into the left side of the engine block. These marks are read from left to right, corresponding with cylinder number 1, 2, 3, 4, 5, 6.

Engine block cylinder bore diameter grade markings correspond to specific cylinder bore diameters. The chart below identifies the two engine block grade markings and their associated cylinder bore diameters.

Engine Block Marking	Cylinder Bore Size mm (in.)
1	95.995 Â± 0.005 mm (3.7793 Â± 0.0002 in.)
2	96.005 Â± 0.005 mm (3.7797 Â± 0.0002 in.)

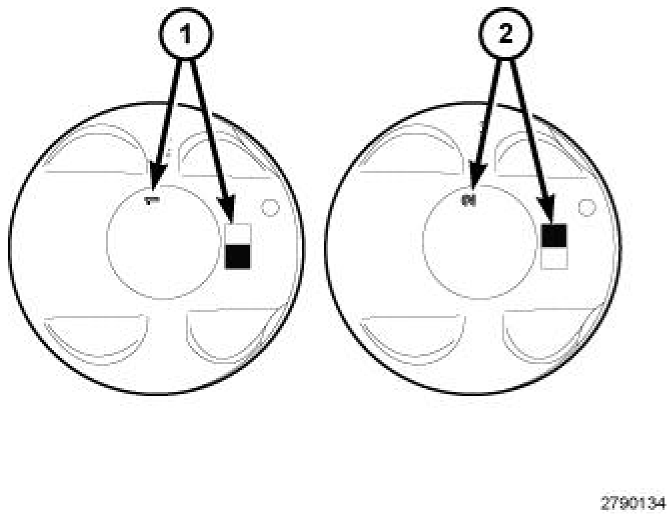

Fig. 397: Piston Size Located On Piston Crown
Courtesy of CHRYSLER GROUP, LLC

The piston is marked with the piston size (1 and 2) on the piston crown. The pistons are available in two different sizes in order to achieve the desired oil clearance. Select the piston size that corresponds to the engine block cylinder bore diameter grade markings for each cylinder.

Pistons are available in two sizes. The chart below identifies the two piston sizes.

Piston Marking	Size mm (in.)	
	Metal to Metal	Metal to Coating
1	95.995 Â± 0.005 mm (3.7793 Â± 0.0002 in.)	95.970 - 96.000 mm (3.7783 - 3.7795 in.)
2	95.965 Â± 0.005 mm (3.7781 Â± 0.0002 in.)	95.980 - 96.010 mm (3.7787 - 3.7835 in.)

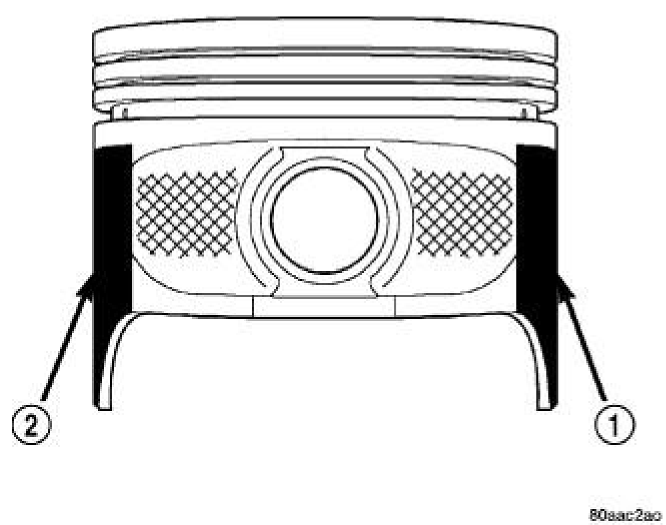

Fig. 398: Identifying Coating Material On Piston
Courtesy of CHRYSLER GROUP, LLC

NOTE: **Typical coated piston shown in illustration.**

The coated pistons are serviced with the piston pin and connecting rod pre-assembled. The coating material (1 and 2) is applied to the piston after the final piston machining process. Piston installation into the cylinder bore requires slightly more pressure than that required for non-coated pistons. The bonded coating on the piston will give the appearance of a line-to-line fit with the cylinder bore.

CONNECTING ROD SIDE CLEARANCE

DIAL INDICATOR

1. Mount Dial Indicator Set (special tool #C-3339A, Set, Dial Indicator) to a stationary point on the engine. Locate the probe perpendicular to and resting against the connecting rod cap being checked.
2. Move the connecting rod all the way to the rear of its travel.

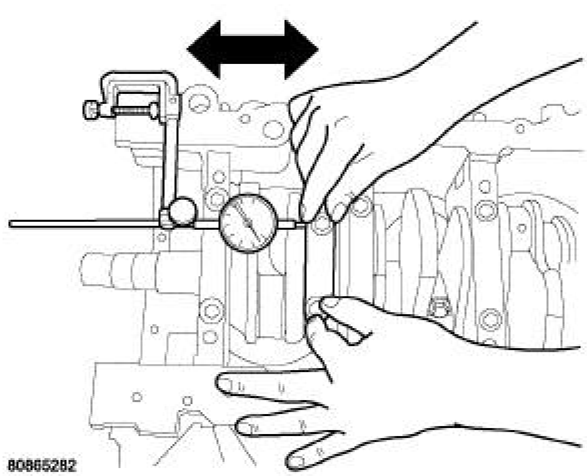

Fig. 399: Measuring Connecting Rod Side Clearance
Courtesy of CHRYSLER GROUP, LLC

3. Zero the dial indicator.
4. Move the connecting rod forward to the limit of travel and read the dial indicator. Compare the measured side clearance to the specification. Refer to **ENGINE SPECIFICATIONS**.
5. Repeat this procedure for each connecting rod. Rotate the crankshaft for connecting rod accessibility.

FEELER GAUGE

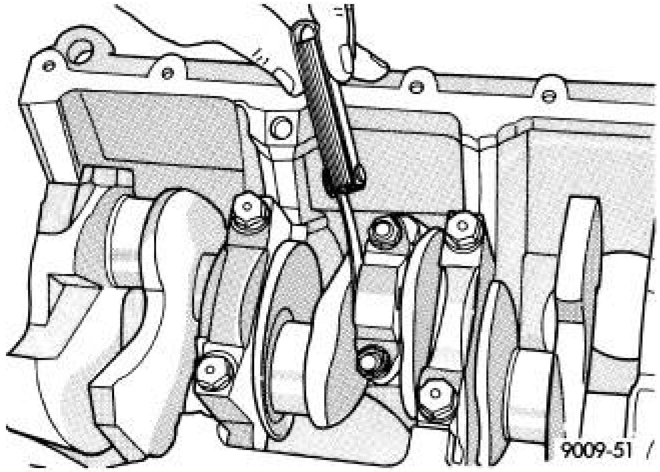

Fig. 400: Measuring Gap Between Connecting Rod & Crankshaft Journal Flange

1. Slide a snug-fitting feeler gauge between the connecting rod and crankshaft journal flange. Compare the measured side clearance to the specification. Refer to **ENGINE SPECIFICATIONS**.
2. Repeat this procedure for each connecting rod. Rotate the crankshaft for connecting rod accessibility.

REMOVAL

REMOVAL

1. Remove the oil pans, engine timing cover and cylinder heads. Refer to **CYLINDER HEAD, REMOVAL**.

2. Remove the engine oil pump. Refer to **PUMP, ENGINE OIL, REMOVAL**.
3. Remove the eight main bearing cap bolts from the windage tray in the sequence shown in illustration and remove the windage tray (1).

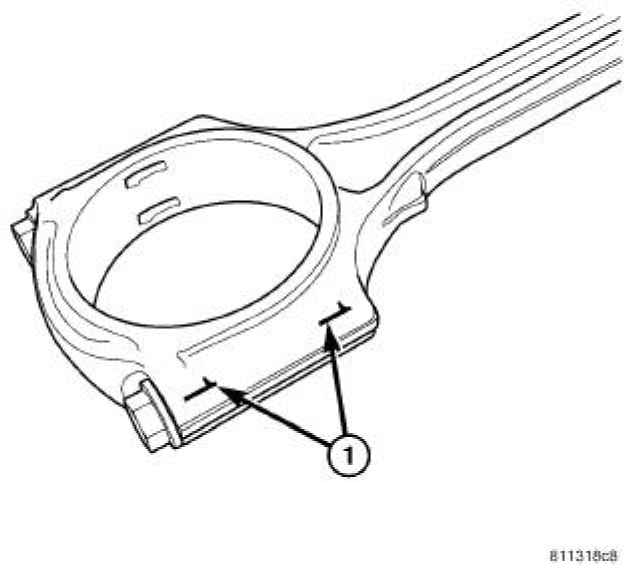

Fig. 402: Connecting Rod To Cylinder Identification
Courtesy of CHRYSLER GROUP, LLC

4. If necessary, remove the top ridge of the cylinder bores with a reliable ridge reamer before removing the pistons from the engine block. **Be sure to keep the tops of pistons covered during this operation.** Pistons and connecting rods must be removed from the top of the engine block. When removing piston and connecting rod assemblies from the engine, rotate the crankshaft clockwise so that each connecting rod is centered in the cylinder bore.

CAUTION: **DO NOT use a number stamp or a punch to mark connecting rods or caps, as damage to connecting rods could occur**

NOTE: **Connecting rods and bearing caps are not interchangeable and should be marked before removing to ensure correct reassembly.**

5. Mark connecting rod and bearing cap positions (1) using a permanent ink marker or scribe tool.

NOTE: **Typical V6 engine configuration shown in illustration.**

CAUTION: **Care must be taken not to damage the fractured rod and cap joint face surfaces, as engine damage may occur.**

6. Remove the connecting rod cap bolts (5) and the connecting rod cap (4). Discard the cap bolts.

CAUTION: Care must be taken not to nick crankshaft journals, as engine damage may occur.

7. Remove the plastic guide plates (3) from the Guide Pins (special tool #8189, Guide Pins) (7) and install the Guide Pins to the connecting rod being removed.

CAUTION: Avoid contact with the piston oil cooler jet(s). Positioning of the oil cooler jet(s) is critical for proper engine operation.

8. Remove the piston and connecting rod (1) from cylinder bore.
9. Repeat the previous steps for each piston being removed.
10. Immediately after piston and connecting rod removal, reinstall the bearing cap (4) on the mating connecting rod to prevent damage to the fractured cap and rod surfaces.
11. If required, remove the piston rings. Refer to **RING(S), PISTON, REMOVAL**.
12. Repeat the previous steps for each piston being removed.

CLEANING

CLEANING

CAUTION: DO NOT use a wire wheel or other abrasive cleaning devise to clean the pistons or connecting rods. The pistons have a Moly coating, this coating must not be damaged.

CAUTION: Do not remove the piston pin from the piston and connecting rod assembly.

1. Clean the pistons in warm water using a suitable cleaning solvent and then towel dry.
2. Use a wood or plastic scraper to clean the ring land grooves.

INSPECTION

INSPECTION

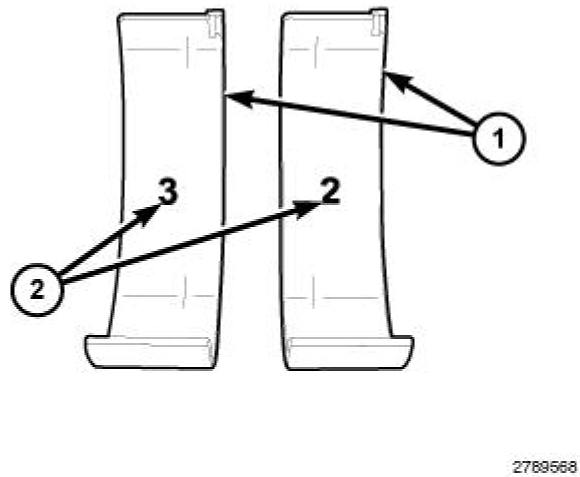

Fig. 404: Connecting Rod Bearing Shells & Bearing Size
Courtesy of CHRYSLER GROUP, LLC

1. Wipe the inserts (1) clean.
2. Inspect the inserts for abnormal wear patterns, scoring, grooving, fatigue, pitting and for metal or other foreign material imbedded in the lining.
3. Inspect the back of the inserts for fractures, scrapes, or irregular wear patterns.
4. Inspect the insert locking tabs for damage.
5. Replace any bearing that shows abnormal wear. Refer to **BEARING(S), CONNECTING ROD, STANDARD PROCEDURE**.

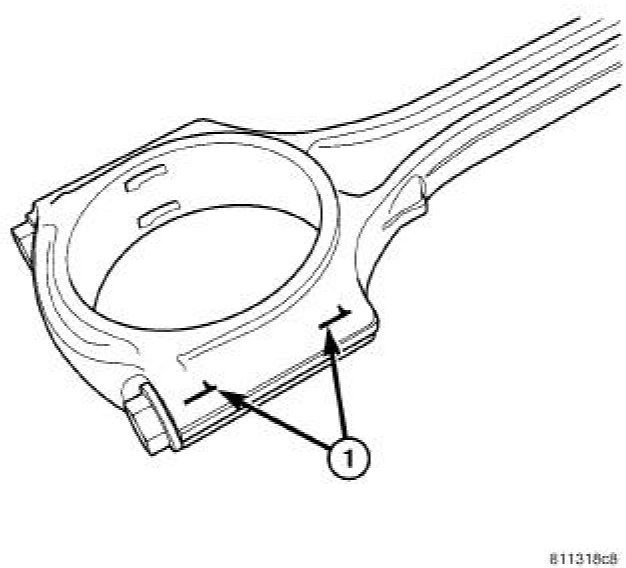

Fig. 405: Connecting Rod To Cylinder Identification
Courtesy of CHRYSLER GROUP, LLC

6. Inspect the connecting rod bearing bores for signs of scoring, nicks and burrs.

NOTE: **Misaligned or bent connecting rods can cause abnormal wear on pistons, piston rings, cylinder walls, connecting rod bearings and crankshaft connecting rod journals. If wear patterns or damage to any of these components indicate the probability of a misaligned connecting rod, inspect it for correct rod alignment.**

7. Replace misaligned, bent or twisted connecting rods.

NOTE: **Connecting rods are serviced with the piston pre-assembled. The pistons are "select fit" to achieve proper oil clearance. Refer to STANDARD PROCEDURE.**

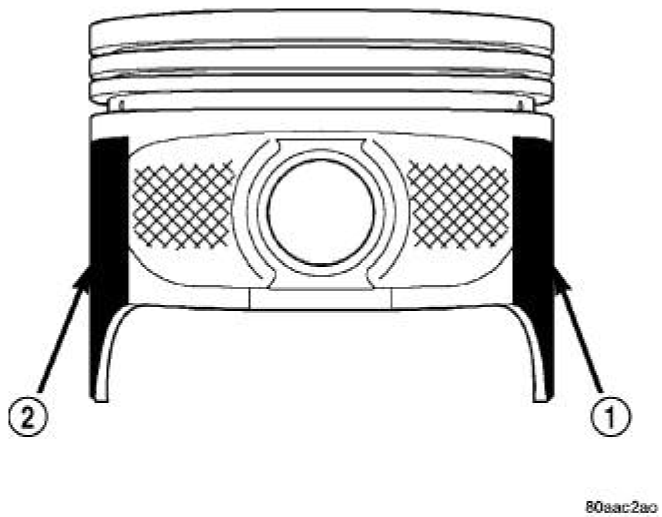

Fig. 406: Identifying Coating Material On Piston
Courtesy of CHRYSLER GROUP, LLC

NOTE: **Typical coated piston shown in illustration.**

8. Inspect the piston for scoring or scraping marks in the piston skirts. Check the ring lands for cracks and/or deterioration.
9. Check the piston for taper and out of round shape.

NOTE: **The coating material (1 and 2) is applied to the piston after the final piston machining process. Measuring the outside diameter of a coated piston will not provide accurate results. Therefore measuring the inside diameter of the cylinder bore with a dial Bore Gauge is MANDATORY . Refer to INSPECTION.**

10. Compare the measured cylinder bore diameter to the engine block cylinder bore grade marking chart. Select the piston size that corresponds to the engine block markings for each cylinder to provide the proper oil clearance. Refer to STANDARD PROCEDURE.

NOTE: **Piston installation into the cylinder bore requires slightly more pressure than that required for non-coated pistons. The bonded coating on the piston will give the appearance of a line-to-line fit with the cylinder bore.**

NOTE: **The coated pistons will be serviced with the piston pin and connecting rod pre-assembled.**

INSTALLATION

INSTALLATION

1. If required, select and fit new piston and connecting rod assemblies to the engine block. Refer to **STANDARD PROCEDURE**.
2. If required, select and fit new bearings to the connecting rod. Refer to **BEARING(S), CONNECTING ROD, STANDARD PROCEDURE**.
3. If required, hone the cylinder bores. Refer to **ENGINE BLOCK, STANDARD PROCEDURE**.
4. If removed, install the piston rings. Refer to **RING(S), PISTON, INSTALLATION**.

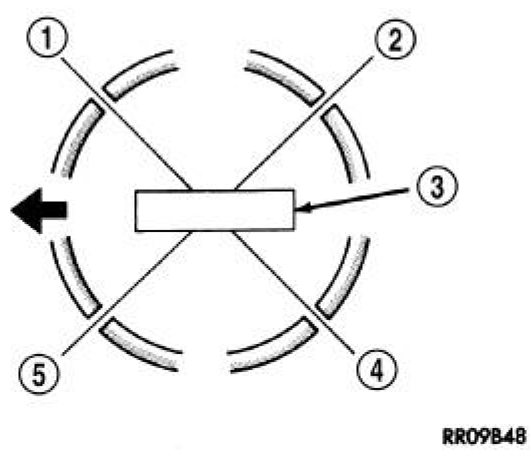

Fig. 407: Piston Ring End Gap Position

5. Position the piston ring end gaps as follows:
   - Oil ring expander gap (5)
   - Oil ring lower side rail end gap (4)
   - Oil ring upper side rail end gap (1)
   - No. 2 (intermediate) ring end gap (5)
   - No. 1 (upper) ring end gap (2)

NOTE: **Typical V6 engine configuration shown in illustration.**

NOTE: **Ensure the position of the ring end gaps does not change when installing the ring compressor.**

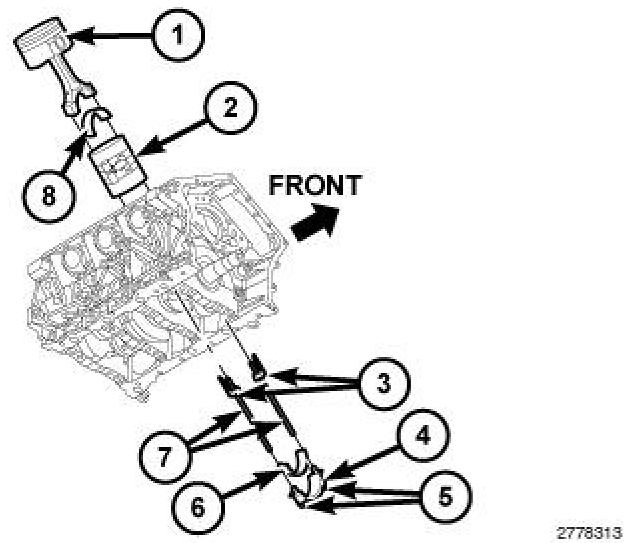

Fig. 408: Piston, Connecting Rod Cap, Bolts, Plastic Guide Plates & Guide Pins

6. Lubricate the piston rings with clean engine oil. Position Piston Compressor (special tool #C-385, Compressor, Piston) (2) over the piston and rings. Tighten the compressor (2).

NOTE: **Install the rod bearings in pairs. Do not mix sizes or use a new bearing half with an old bearing half.**

7. Install the bearing shell (8) on the connecting rod with the tang inserted into the machined groove in the rod. Lubricate the bearing surface with clean engine oil.
8. Remove the plastic guide plates (3) from the Guide Pins (special tool #8189, Guide Pins) (7) and install the Guide Pins to the connecting rod being installed.

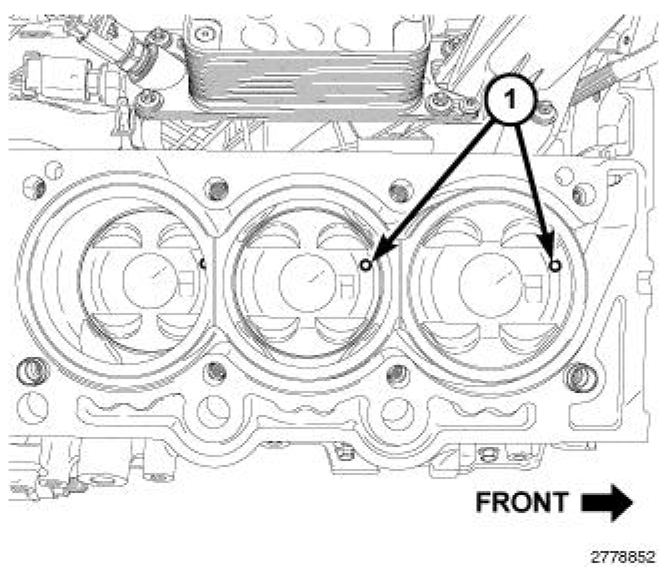

Fig. 409: Piston Installation Position

NOTE: **Right cylinder bank shown in illustration, left cylinder bank similar.**

9. The pistons crowns are stamped with a mark (1) indicating installation position. This mark must be positioned toward the front of engine on both cylinder banks.
10. Wipe the cylinder bore clean and lubricate with clean engine oil.
11. Rotate the crankshaft until the connecting rod journal is on the center of cylinder bore.

CAUTION: Avoid contact with the piston oil cooler jet(s). Positioning of the oil cooler jet(s) is critical for proper engine operation.

12. Insert the piston and connecting rod into the cylinder bore and carefully position the guide pins over the crankshaft journal.
13. Tap the piston down in the cylinder bore using a hammer handle while guiding the connecting rod into position over the rod journal.

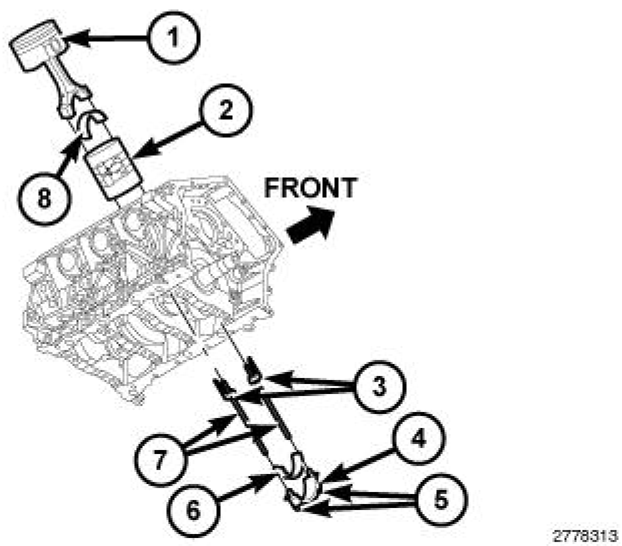

Fig. 410: Piston, Connecting Rod Cap, Bolts, Plastic Guide Plates & Guide Pins

NOTE: Typical V6 engine configuration shown in illustration.

CAUTION: The connecting rod bolts must not be reused. Always replace the connecting rod bolts whenever they are loosened or removed.

14. Install the bearing shell (6) on the connecting rod cap (4) with the tang inserted into the machined groove in the cap. Lubricate the bearing surface with clean engine oil.

NOTE: Do not lubricate the threads of the connecting rod cap bolts (5).

15. Install the connecting rod cap and bearing with the tang on the same side as the rod. Tighten the **NEW** connecting rod cap bolts (5) to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
16. If required, check the connecting rod side clearance. Refer to **STANDARD PROCEDURE**.
17. Repeat the previous steps for each piston being installed.

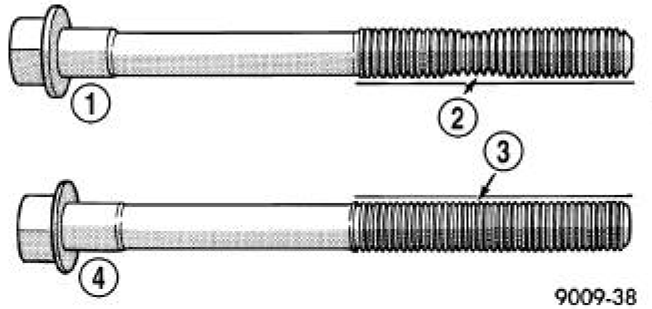

Fig. 411: Checking Cylinder Head Bolts For Stretching (Necking)

CAUTION: The main bearing cap bolts are tightened using a torque plus angle procedure. The bolts must be examined BEFORE reuse. If the threads are necked down the bolts must be replaced.

18. Check the main bearing cap bolts for necking by holding a scale or straight edge against the threads. If all the threads do not contact the scale (2) the bolt must be replaced.

19. Install the windage tray with eight main bearing cap bolts. Tighten the bolts in the sequence shown in illustration to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
20. Install the engine oil pump and oil pump pick-up. Refer to **PUMP, ENGINE OIL, INSTALLATION**.
21. Install the cylinder heads, engine timing cover and oil pans. Refer to **CYLINDER HEAD, INSTALLATION**.
22. If removed, install the oil filter and fill the engine crankcase with the proper oil to the correct level. Refer to **STANDARD PROCEDURE**.
23. Fill the cooling system. Refer to **STANDARD PROCEDURE** .
24. Operate the engine until it reaches normal operating temperature. Check cooling system for correct fluid level. Refer to **STANDARD PROCEDURE** .

1. Position the front crankshaft oil seal (3) to engine timing cover.
2. Align the Front Crankshaft Seal Installer (special tool #10199, Installer, Crankshaft Front Oil Seal) (1) to the flywheel key on the crankshaft and against the front crankshaft oil seal (3).

CAUTION: Only tighten the crankshaft vibration damper bolt until the oil seal is seated in the cover. Overtightening of the bolt can crack the front timing

cover.

3. Install and tighten the crankshaft vibration damper bolt (2) until the crankshaft oil seal is seated in the engine timing cover.
4. Install the crankshaft vibration damper. Refer to **DAMPER, VIBRATION, INSTALLATION**.
5. Install the serpentine belt. Refer to **BELT, SERPENTINE, INSTALLATION** .

The rear crankshaft oil seal is incorporated into the seal retainer (2) and can not be removed from the retainer. The rear crankshaft oil seal and seal retainer (2) are serviced as an assembly.

1. Remove the flexplate. Refer to **FLEXPLATE, REMOVAL**.
2. Remove the upper oil pan. Refer to **PAN, OIL, REMOVAL**.
3. Remove the eight seal retainer attaching screws (1).
4. Remove and discard the seal retainer (2).

INSTALLATION

INSTALLATION

CAUTION: **The rear crankshaft oil seal (2) and retainer (1) are an assembly. To avoid damage to the seal lip, DO NOT remove the seal protector (3) from the rear crankshaft oil seal before installation onto the engine.**

CAUTION: **Whenever the crankshaft is replaced, the rear crankshaft oil seal must also be replaced. Failure to do so may result in engine fluid leakage.**

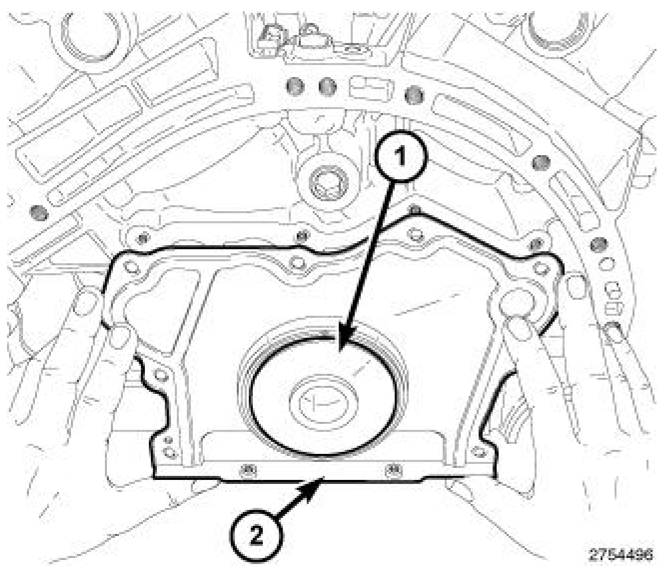

Fig. 419: Oil Seal Retainer Assembly & Seal Protector

1. Inspect the crankshaft to make sure there are no nicks or burrs on the seal surface.
2. Clean the engine block sealing surfaces thoroughly.

NOTE: **It is not necessary to lubricate the seal or the crankshaft when installing the seal retainer. Residual oil following installation can be mistaken for**

seal leakage.

3. Carefully position the oil seal retainer assembly (2), and seal protector (1) on the crankshaft and push firmly into place on the engine block (during this step, the seal protector will be pushed from the rear oil seal assembly as a result of installing the rear oil seal).

5. Install the eight seal retainer bolts (1) and tighten to the proper specification. Refer to **TORQUE SPECIFICATIONS**.

NOTE: **Make sure that the seal retainer flange is flush with the engine block oil pan sealing surface.**

6. Install the upper oil pan. Refer to **PAN, OIL, INSTALLATION**.
7. Install the flexplate. Refer to **FLEXPLATE, INSTALLATION**.
8. Fill the engine crankcase with the proper oil to the correct level. Refer to **STANDARD PROCEDURE**.

LUBRICATION

DESCRIPTION

DESCRIPTION

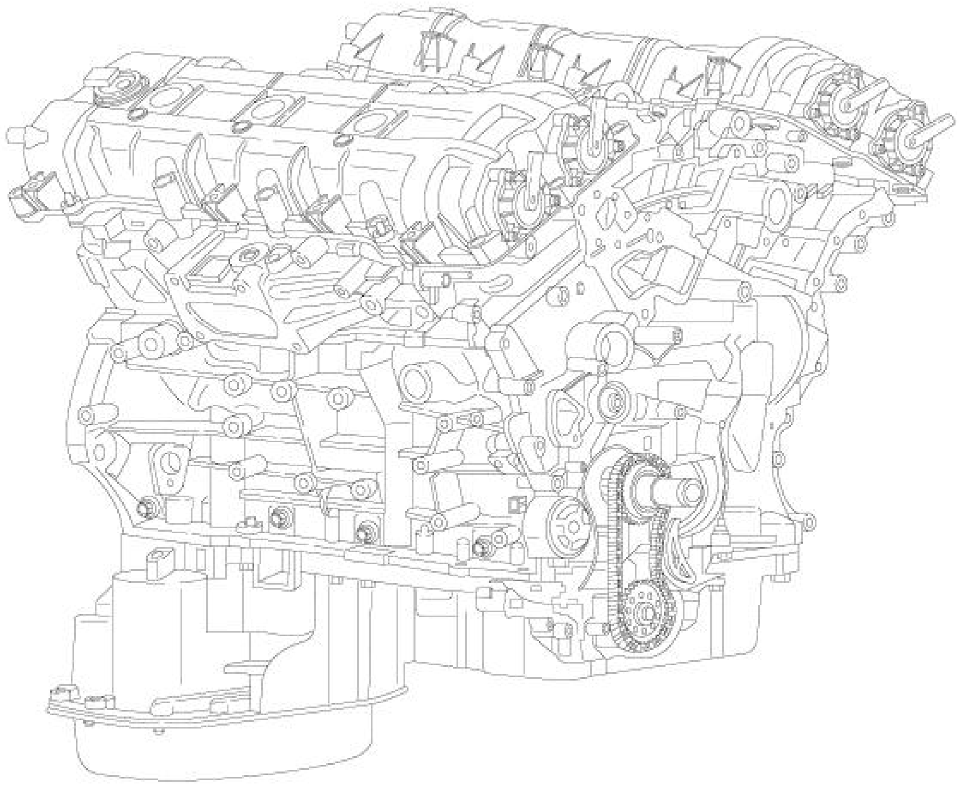

Fig. 451: 3.6L Engine
Courtesy of CHRYSLER GROUP, LLC

The lubrication system is a full flow filtration, pressure feed type lubrication system:

- The oil pump is mounted to the bottom of the cylinder block and chain driven by the crankshaft sprocket.
- The oil pump pick-up tube is attached to the oil pump and supported at the windage tray.
- There are three oil gallery plugs installed in the engine block.
- A system oil pressure sensor allows oil pressure to be monitored with a diagnostic scan tool.
- The oil pressure and oil temperature sensors are located on the oil filter housing assembly which is mounted to the top of the engine block between the cylinder heads.
- The oil cooler is mounted to the oil filter housing.
- There is a pressure relief valve in the oil pump that is only activated on a cold start or for emergency relief since the oil pump output is self-regulating.
- There are three piston oil cooler jets mounted to the engine block that cools two pistons.

OPERATION

OPERATION

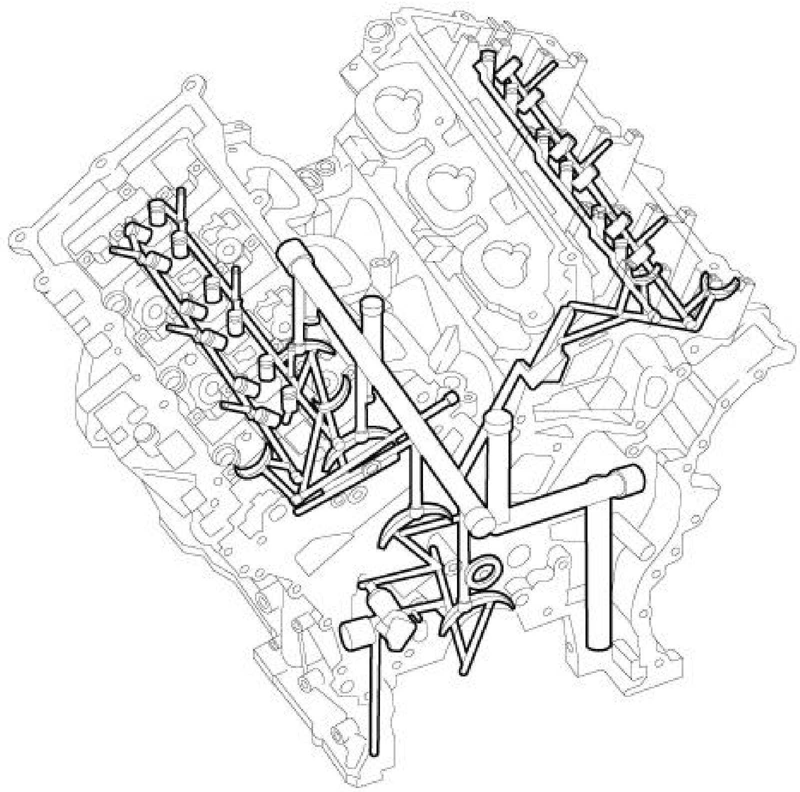

Fig. 452: Engine Lubrication Flow
Courtesy of CHRYSLER GROUP, LLC

Oil Flow:

- The oil from the oil pan is pumped by a vane type oil pump mounted to the bottom of the cylinder block that is chain driven by the crankshaft sprocket
- The oil from the pump travels to the oil filter element and then to the oil cooler assembly
- After the oil has been filtered and cooled, the oil enters the main oil gallery
- The pressurized oil travels through the main gallery to the four main journals to lubricate the crankshaft main bearings
- The pressurized oil travels through the crankshaft main journals to cross-drilling supplying oil to the connecting rod journals
- From the number one main bearing gallery, oil travels to the right secondary chain tensioner and to the primary chain idler shaft
- The main oil gallery also supplies oil to three sets of piston oil cooling jets
- From the cylinder block, the oil flows through the galleys into the left and right cylinder heads
- Left cylinder head oil is supplied to the left secondary timing chain tensioner, camshaft journals and hydraulic lash adjusters
- Right cylinder head oil is supplied to the right camshaft journals and hydraulic lash adjusters
- The camshaft valve lobes and rocker arms are lubricated through a small hole in the rocker arm; oil flows

through the lash adjuster then through the rocker arm and onto the camshaft lobe

- Oil also flows through each of the four forward camshaft bearings into the camshafts and phasers

DIAGNOSIS AND TESTING

ENGINE OIL LEAK

Begin with a thorough visual inspection of the engine, particularly at the area of the suspected leak. If an oil leak source is not readily identifiable, the following steps should be followed:

1. Do not clean or de-grease the engine at this time because some solvents may cause rubber to swell, temporarily stopping the leak.
2. Add an oil soluble dye (use as recommended by manufacturer). Start the engine and let idle for approximately 15 minutes. Check the oil dipstick to make sure the dye is thoroughly mixed as indicated with a bright yellow color under a black light.
3. Using a black light, inspect the entire engine for fluorescent dye, particularly at the suspected area of the oil leak. If the oil leak is found and identified, repair in accordance to the Service Information.
4. If dye is not observed, drive the vehicle at various speeds for approximately 24 km (15 miles), and repeat the inspection.

   If the oil leak source is not positively identified at this time, proceed with the AIR LEAK DETECTION

TEST METHOD.

AIR LEAK DETECTION TEST METHOD

1. Disconnect the make-up air hose from the cylinder head cover. Cap or plug the make-up air hose nipple.
2. Remove the PCV hose from the PCV valve. Cap or plug the PCV valve nipple.
3. Attach an air hose with a pressure gauge and regulator to the dipstick tube.

CAUTION: Do not subject the engine assembly to more than 20.6 kPa (3 PSI) of test pressure.

4. Gradually increase air pressure from 1 psi to 2.5 psi maximum while applying soapy water at the suspected leak source. Adjust the regulator to a suitable test pressure within this range that provides the best bubble generation which will pinpoint the leak source. If the oil leak is detected and identified, repair in accordance with the Service Information.
5. If the leakage occurs at the rear oil seal area, follow the procedures for rear seal area leaks. Refer to **REAR SEAL AREA LEAKS**.
6. If no leaks are detected, turn off the air supply and remove the air hose and all plugs and caps. Install the PCV valve and make-up air hoses.
7. Clean the oil off of the suspect oil leak area using a suitable solvent. Drive the vehicle at various speeds approximately 24 km (15 miles). Inspect the engine for signs of an oil leak by using a black light.

CHECKING ENGINE OIL PRESSURE

1. Disconnect and isolate the negative battery cable.
2. Remove the oil pressure sensor from the oil filter housing. Refer to **SENSOR, OIL PRESSURE, REMOVAL**.

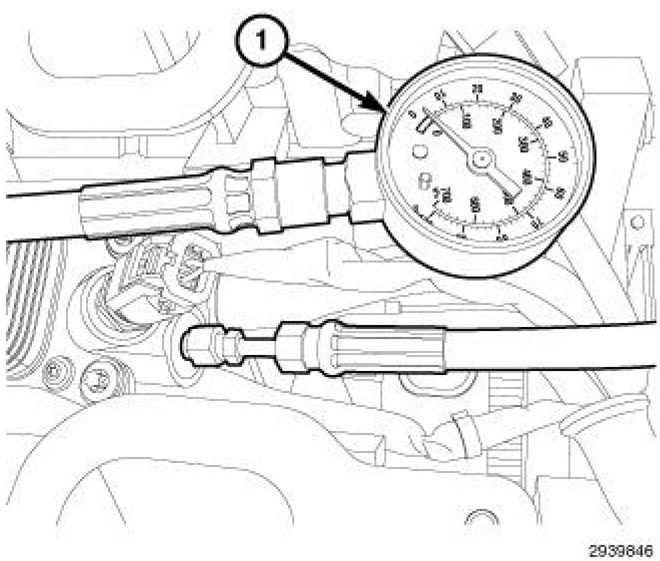

Fig. 453: Pressure Gauge Installed To Oil Pressure Port
Courtesy of CHRYSLER GROUP, LLC

3. Install Pressure Gauge (special tool #C-3292A, Gauge, Pressure) (1) to the oil pressure port. Tighten to 20 N.m (177 in. lbs.).

4. Install the intake manifold. Refer to **MANIFOLD, INTAKE, INSTALLATION**.
5. Connect the negative battery cable. Tighten the nut to the proper specification. Refer to **SPECIFICATIONS** .
6. Start and idle the engine. If oil pressure is 0 at idle, shut off the engine and consult the Engine Lubrication and Diagnostic Table. Refer to **ENGINE LUBRICATION DIAGNOSTIC TABLE**.
7. Run the engine until it reaches normal operating temperature.
8. Verify that the engine has acceptable oil pressure. Refer to **ENGINE SPECIFICATIONS**.

REAR SEAL AREA LEAKS

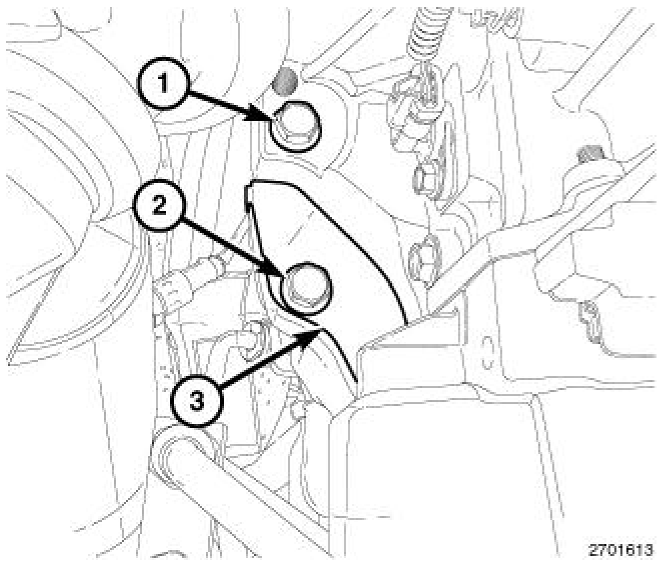

Fig. 454: Side Engine-To-Transmission Bolt, Transmission Dust Shield Retaining Bolt & Dust Shield
Courtesy of CHRYSLER GROUP, LLC

Since it is sometimes difficult to determine the source of an oil leak in the rear seal area of the engine, a more involved inspection is necessary. The following steps should be followed to help pinpoint the source of the leak.

If the leakage occurs at the crankshaft rear oil seal area:

1. Disconnect and isolate the negative battery cable.
2. Raise and support the vehicle. Refer to **HOISTING, STANDARD PROCEDURE** .
3. Remove the bolt (2) and the torque converter dust shield (3).

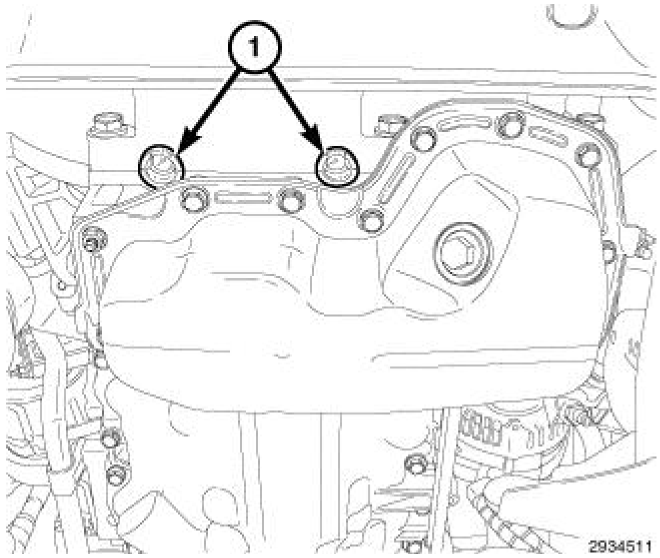

Fig. 455: Rubber Plugs
Courtesy of CHRYSLER GROUP, LLC

4. Remove two rubber plugs (1) covering the rear oil seal retainer flange bolts.
5. Inspect the flexplate and rear of the block for evidence of oil. Use a black light to check for the oil leak:
   a. Circular spray pattern generally indicates seal leakage or crankshaft damage.
   b. Where leakage tends to run straight down, possible causes are a porous block, rear oil seal retainer, oil galley pipe plug and rear seal retainer to oil pan mating surfaces.
6. If no leaks are detected, use the **AIR LEAK DETECTION TEST METHOD**.

CAUTION: Do not subject the engine assembly to more than 20.6 kPa (3 PSI) of test pressure.

7. If the leak is not detected, very slowly turn the crankshaft and watch for leakage. If a leak is detected between the crankshaft and seal while slowly turning the crankshaft, it is possible the crankshaft seal surface is damaged. The seal area on the crankshaft could have minor nicks or scratches that can be polished out with emery cloth.

CAUTION: Use extreme caution when crankshaft polishing is necessary to remove minor nicks or scratches. The crankshaft seal flange is specially machined to complement the function of the rear oil seal.

8. For bubbles that remain steady with shaft rotation, no further inspection can be done until disassembled. Refer to **SEAL, CRANKSHAFT OIL, REAR, REMOVAL**.

The oil cooler (1) is attached to the top of the oil filter housing (2) which is located in the V of the cylinder block. The oil cooler is a plate style coolant-to-oil heat exchanger.

OPERATION

OPERATION

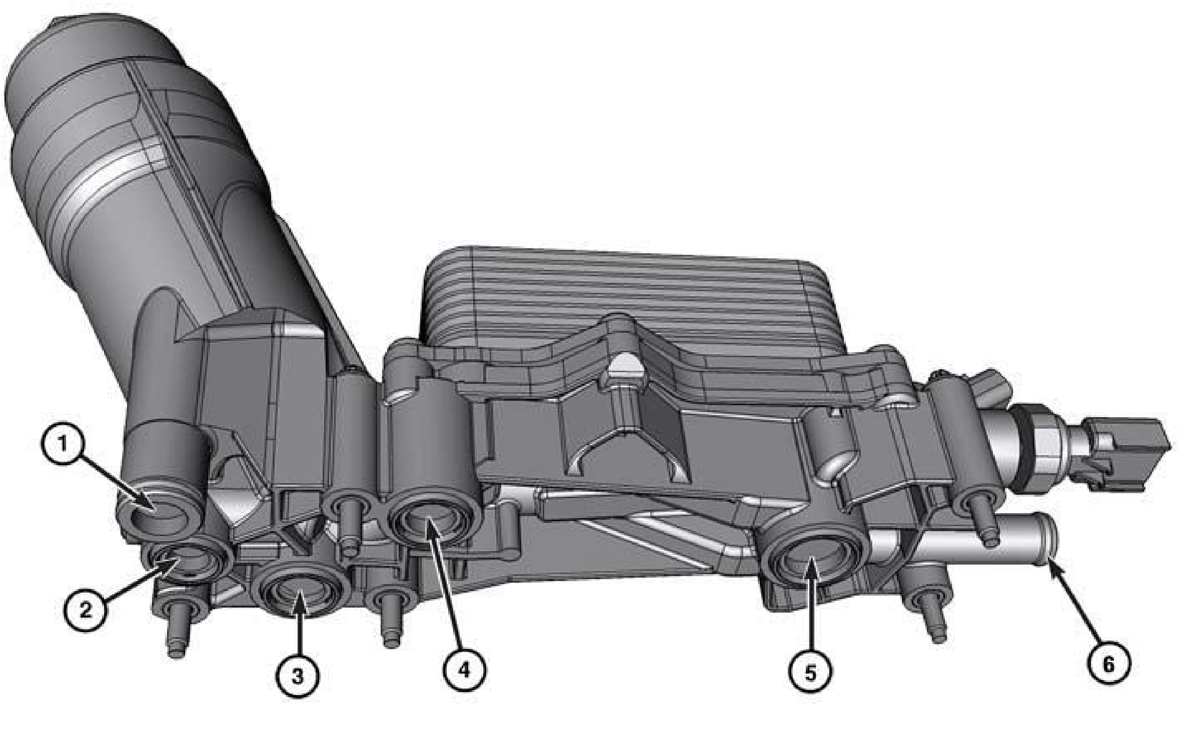

Fig. 457: Oil Flow Locations
Courtesy of CHRYSLER GROUP, LLC

Oil flows from the engine oil pump to the oil filter housing inlet (1) and to the oil filter element located within the oil filter housing. After the oil is filtered it travels internally through the engine oil cooler and then to the main oil gallery (5).

Coolant flows from the right cylinder block water jacket (3) and from the left cylinder block water jacket (4) into the housing. The coolant flows through the oil cooler and exits the housing from the rear hose nipple (6) where it is returned to the water pump. A coolant by-pass in the housing is designed to direct excessive coolant flow around the oil cooler for continuous circulation.

FILTER, ENGINE OIL

REMOVAL

REMOVAL

All engines are equipped with a high quality full-flow, disposable type oil filter. Chrysler Corporation recommends a MoparÂ® or equivalent oil filter be used.

CAUTION: **When performing an engine oil change, the oil filter cap must be removed. Removing the oil filter cap releases oil held within the oil filter cavity and allows it to drain into the sump. Failure to remove the cap prior to reinstallation of the drain plug will not allow complete draining of the used engine oil.**

HOUSING, OIL FILTER

DESCRIPTION

DESCRIPTION

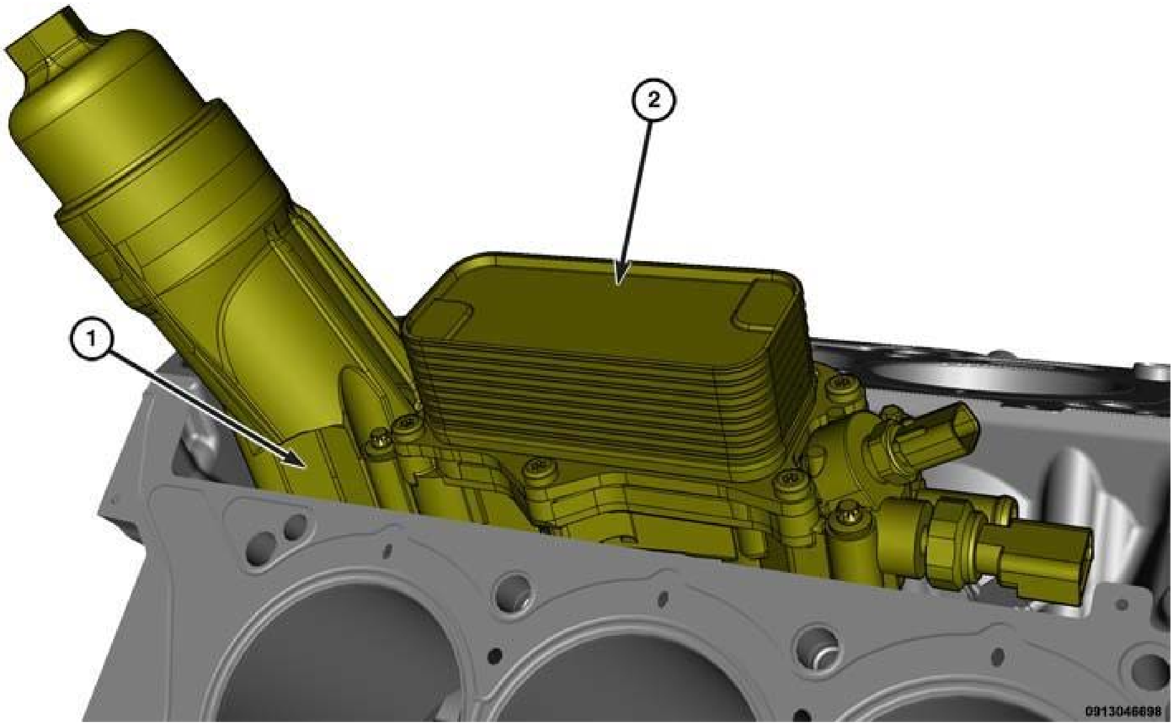

Fig. 466: Oil Filter Housing & Engine Oil Cooler

The oil filter housing (1) is located in the V of the cylinder block. The oil filter element is located within the housing and the engine oil cooler (2) is attached to the top of the housing. Both the oil pressure and oil temperature sensors are located at the rear of the housing.

OPERATION

OPERATION

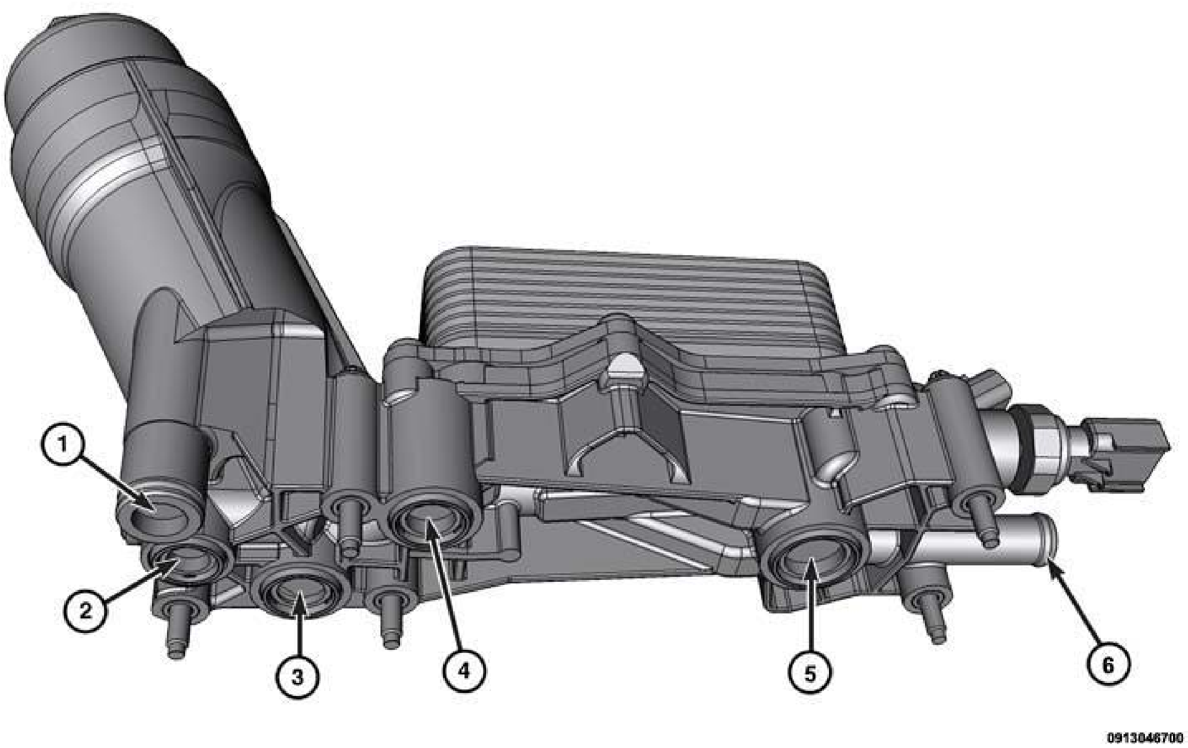

Fig. 467: Oil Flow Locations

Oil flows from the engine oil pump to the oil filter housing inlet (1) and to the oil filter element located within the oil filter housing. After the oil is filtered and then cooled it travels to the main oil gallery (5). An oil filter by-pass is built into the housing and is not serviceable. Removing the oil filter cap from the housing allows oil to drain from the oil filter cavity into to the crankcase (2).

Coolant flows from the right cylinder block water jacket (3) and from the left cylinder block water jacket (4) into the housing. The coolant flows through the oil cooler and exits the housing from the rear hose nipple (6) where it is returned to the water pump. A coolant by-pass in the housing is designed to direct excessive coolant flow around the oil cooler for continuous circulation.

JET, PISTON OIL COOLER

DESCRIPTION

DESCRIPTION

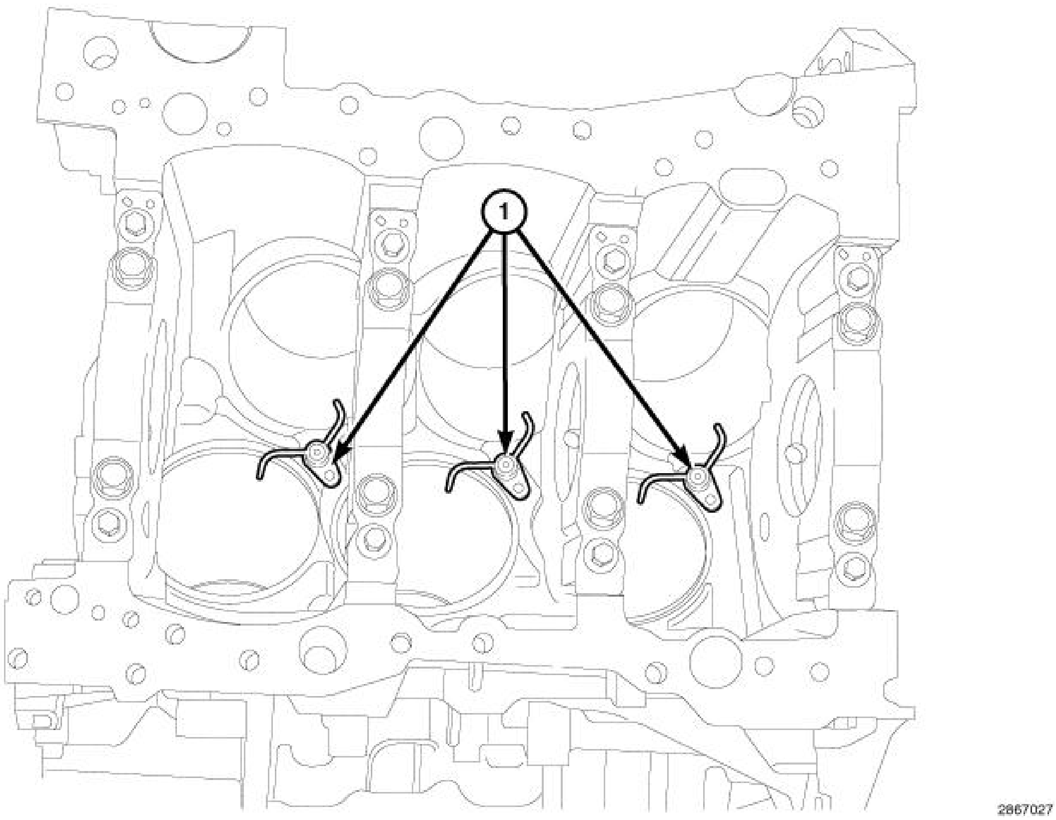

Fig. 477: Engine Blocked-Mounted Oil Jets

The Piston Oil Cooler Jet (1) is used to aid in the cooling of the pistons and the cylinder walls. There are three Piston Oil Cooler Jets used. Each jet is supplied oil by the main oil gallery. The oil is sprayed upwards onto the bottom of the pistons and sides of the cylinder walls. A Piston Oil Cooler Jet is mounted to the engine block under each pair of opposing cylinders.

Each jet has a check valve that closes below 241 kPa (35 psi) to maintain ample oil pressure at idle. All three oil jets are identical and seal to the engine block using an O-ring and fastener.

OIL

STANDARD PROCEDURE

STANDARD PROCEDURE - ENGINE OIL AND FILTER CHANGE

WARNING: New or used engine oil can be irritating to the skin. Avoid prolonged or repeated skin contact with engine oil. Contaminants in used engine oil, caused by internal combustion, can be hazardous to your health. Thoroughly wash exposed skin with soap and water. Do not wash skin with gasoline, diesel fuel, thinner, or solvents, health problems can result. Do not pollute, dispose of used engine oil properly. Contact your dealer or government agency for location of collection center in your area.

Change the engine oil and filter at mileage and time intervals described in the Maintenance Schedule. Refer to MAINTENANCE SCHEDULES, DESCRIPTION .

CAUTION: When performing an engine oil change, the oil filter cap must be removed. Removing the oil filter cap releases oil held within the oil filter cavity and allows it to drain into the sump. Failure to remove the cap prior to reinstallation of the drain plug will not allow complete draining of the used engine oil.

1. Run the engine until achieving normal operating temperature.
2. Position the vehicle on a level surface and turn the engine off.
3. Remove the engine oil filter. Refer to FILTER, ENGINE OIL, REMOVAL.

OIL FILTER SPECIFICATION

All engines are equipped with a high quality full-flow, disposable type oil filter. When replacing oil filter, use a MoparÂ® filter or equivalent.

USED ENGINE OIL DISPOSAL

Care should be exercised when disposing of used engine oil after it has been drained from a vehicle engine. Refer to the WARNING listed above.

PAN, OIL

DESCRIPTION

DESCRIPTION

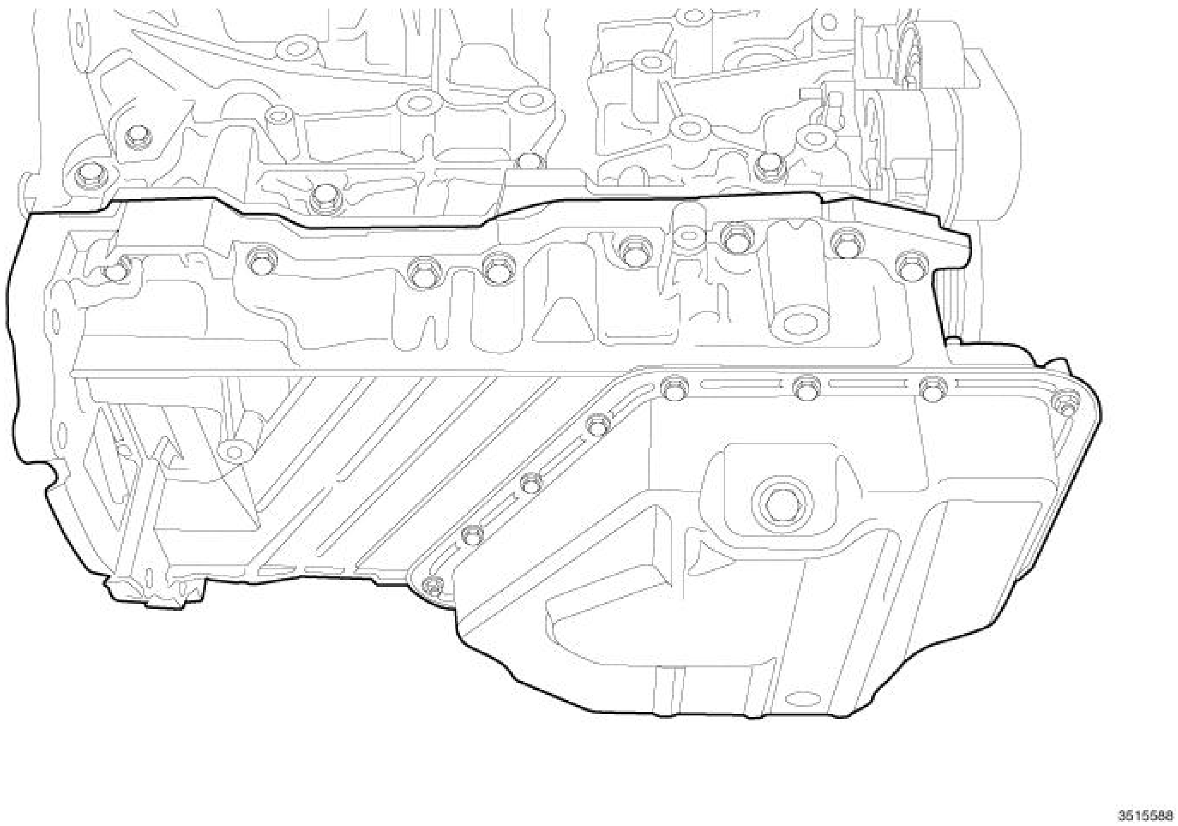

Fig. 487: Upper & Lower Oil Pan
Courtesy of CHRYSLER GROUP, LLC

There is an upper and lower oil pan. The upper oil pan is cast aluminum and also serves as the lower end structural support. The lower pan is a stamped steel design. Both upper and lower oil pans are sealed using MoparÂ® Threebond Engine RTV Sealant. The lower oil pan must be removed in order to access all of the upper oil pan attaching bolts.

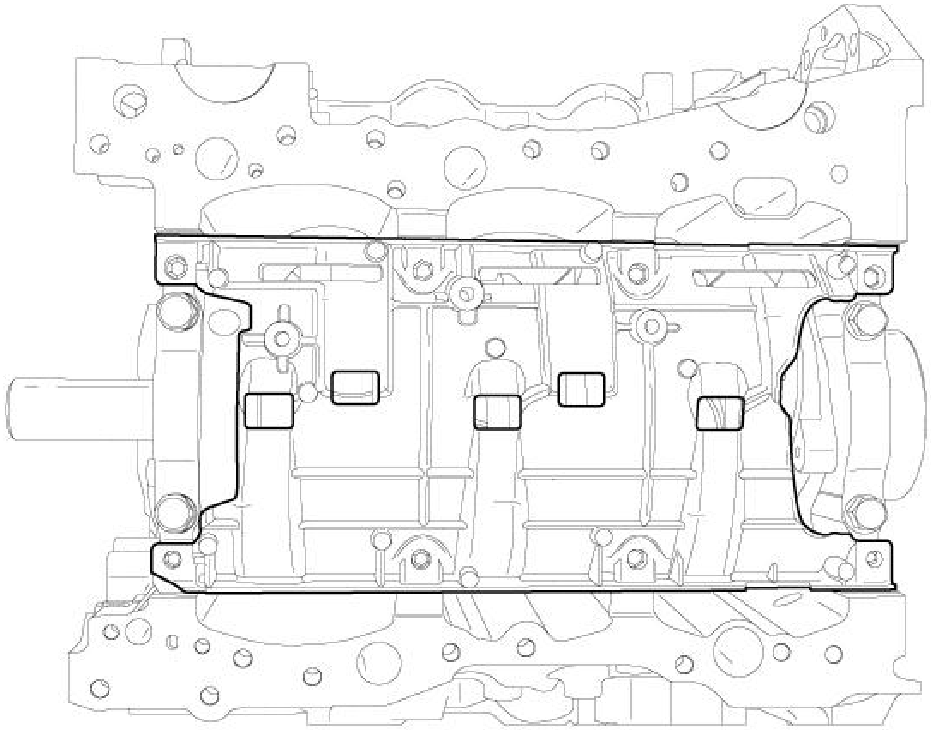

Fig. 488: Windage Tray
Courtesy of CHRYSLER GROUP, LLC

CAUTION: Do not attempt to support the weight of the engine on the windage tray. The windage tray is a thin cast aluminum construction and can be easily damaged.

The high pressure die cast aluminum windage tray is mounted to the main bearing caps and is designed to keep oil off of the connecting rods as the crankshaft rotates. When the oil is kept off the connecting rods, the engine rotates easier and oil foaming decreases. Like the oil pan, the windage tray is designed to stiffen the lower end of the engine. The tray is directional and the main bearing cap bolts hold it in place.

NOTE: **The lower oil pan must be removed to access all of the upper oil pan retaining bolts.**

4. Remove twelve bolts (4), two studs (2) and two nuts (3) from the flange of the lower oil pan (1).

CAUTION: **Do not pry on the lower oil pan flange. There are no designated pry points for lower oil pan removal. Prying on only one or a few locations could bend the flange and damage the pan.**

5. Using a gasket scraper or equivalent, loosen the seal around the lower oil pan in order to shear the sealant

bond and remove the pan.

6. Remove all residual sealant from the upper and lower oil pans and clean the mating surfaces with isopropyl alcohol in preparation for sealant application. Refer to **PAN, OIL, CLEANING**.

CLEANING

CLEANING

CAUTION: Clean the upper and lower oil pans, timing chain cover, rear seal retainer and engine block mating surfaces thoroughly with isopropyl alcohol in preparation for sealant application. All surfaces that seal with RTV must be oil and contamination free to ensure proper adhesion of the RTV to the mating surface

to prevent leaks.

1. Clean the oil pan in solvent and wipe dry with a clean cloth.

CAUTION: Do not use oil based liquids, wire brushes, abrasive wheels or metal scrapers to clean the engine gasket surfaces. Use only isopropyl (rubbing)

alcohol, along with plastic or wooden scrapers. Improper gasket surface preparation may result in engine fluid leakage.

2. Remove all residual sealant (1) from the upper and lower oil pans. Refer to **ENGINE GASKET SURFACE PREPARATION**.

INSTALLATION

LOWER

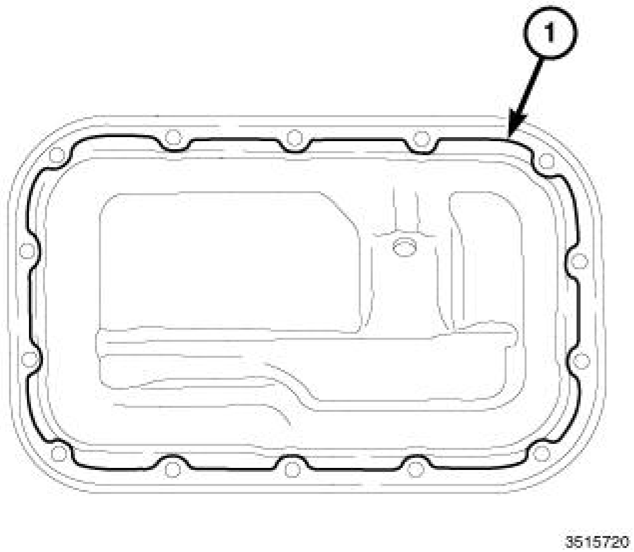

Fig. 505: Locating Sealant On Lower Oil Pan
Courtesy of CHRYSLER GROUP, LLC

CAUTION: **Engine assembly requires the use of a unique sealant that is compatible with engine oil. Using a sealant other than MoparÃ® Threebond Engine RTV Sealant may result in engine fluid leakage.**

CAUTION: **Following the application of MoparÃ® Threebond Engine RTV Sealant to the gasket surfaces, the components must be assembled within 20 minutes and the attaching fasteners must be tightened to specification within 45 minutes. Prolonged exposure to the air prior to assembly may result in engine fluid leakage.**

1. Clean the upper and lower oil pan mating surfaces with isopropyl alcohol in preparation for sealant application. Refer to **PAN, OIL, CLEANING**.
2. Apply a 2 to 3 mm wide bead of MoparÃ® Threebond Engine RTV Sealant (1) to the lower oil pan as shown in illustration.

CAUTION: **Following assembly, the MoparÃ® Threebond Engine RTV Sealant must be allowed to dry for 45 minutes prior to adding oil and engine operation. Premature exposure to oil prior to drying may result in engine fluid leakage.**

3. Install two studs (2) into the upper oil pan flange.
4. Install the lower oil pan (1) to the upper oil pan with twelve bolts (4) and two nuts (3) tightened to the proper specification. Refer to TORQUE SPECIFICATIONS.

PUMP, ENGINE OIL

DESCRIPTION

DESCRIPTION

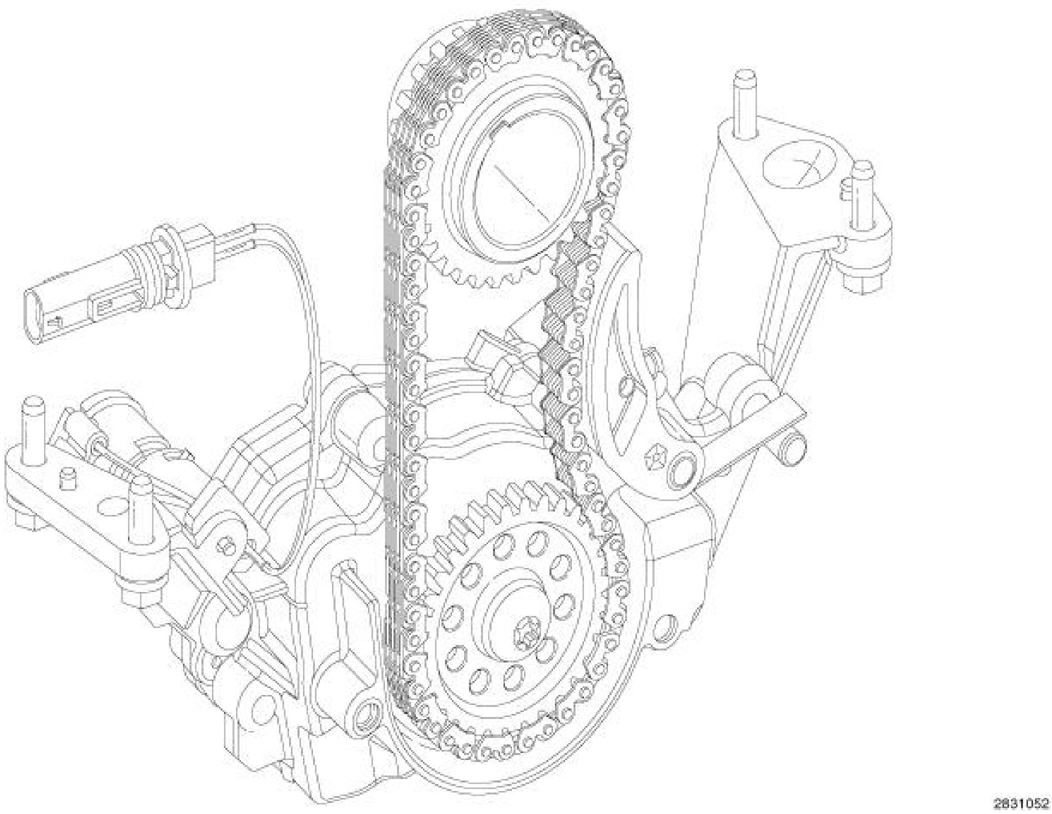

Fig. 525: Oil Pump Chain
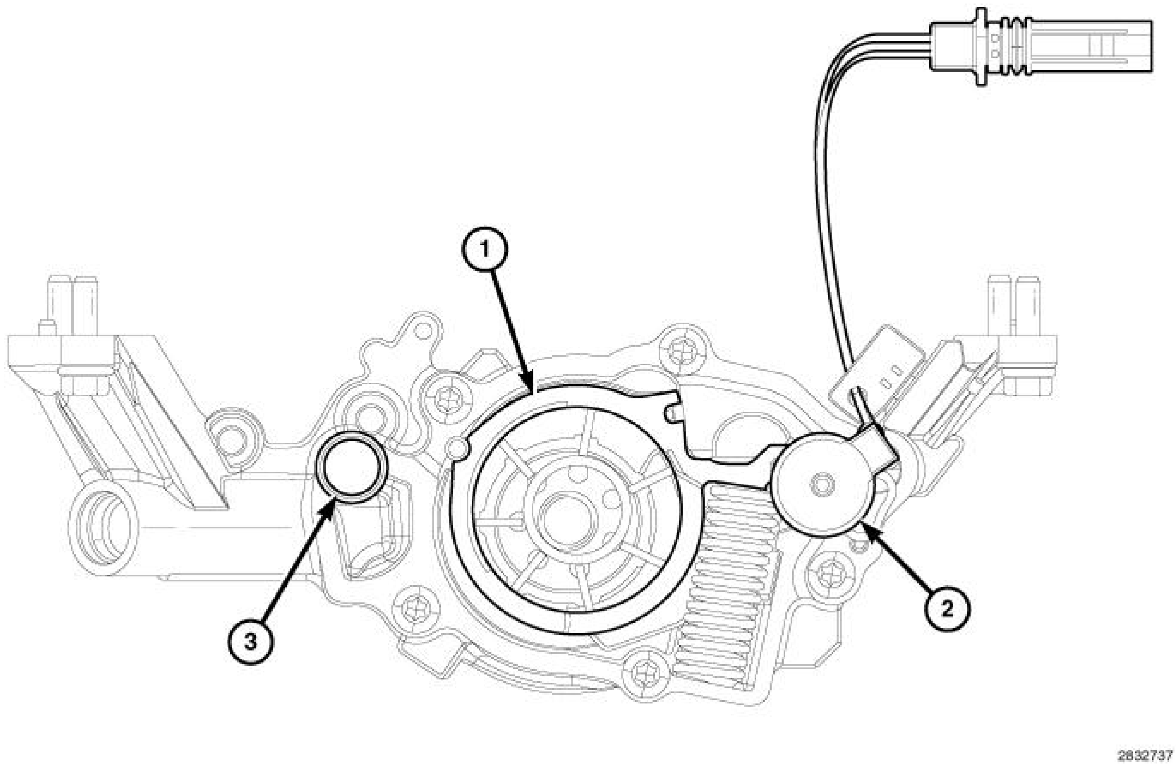
Courtesy of CHRYSLER GROUP, LLC

The vane type engine oil pump is mounted to the underside of the cylinder block and is driven by the oil pump chain off the crankshaft at a 1:1 drive ratio:

- This pump location improves efficiency compared to an on-crankshaft location
- The pump is driven with a silent chain which is tensioned using a spring loaded tensioner
- The pump is not timed to the engine
- An internal mechanical ball and spring type relief valve prevents excess pressure in the engine by dumping oil into the sump and provides emergency protection at conditions such as a cold start with high engine speed
- The pump has a moving slide mechanism for variable displacement capability and an on-off solenoid for two-stage pressure regulation
- The pump and the solenoid are not to be disassembled
- Both components are non-serviceable items and are to be replaced as a complete assembly

OPERATION

OPERATION



[Fig. 526: Moving Element, On/Off Solenoid & Relief Valve](#)
Courtesy of CHRYSLER GROUP, LLC

Oil pump operation as follows:

- The engine oil pump features seven vanes and a moving element (1) that continuously adjusts to maintain a regulated oil pressure supply by varying the displacement of the pump
- The pump has two regulated pressure stages of operation controlled by an on/off solenoid (2)
- Low pressure mode regulation (solenoid on) is approximately 200 kPa (29 psi) and high pressure mode regulation (solenoid off) is approximately 450 kPa (65 psi)
- The Powertrain Control Module (PCM) switches the pump between stages based on engine operating conditions, oil and coolant temperatures, speed and load. Under most typical conditions, the pump will run in low mode from idle up to around 3000 RPM, and switch from low to high mode between 3000 and 4000 RPM
- The maximum oil pressure in the engine is limited to 1000 kPa (145 psi) by the relief valve (3)
- Pressure in the main oil gallery of the engine can be monitored with diagnostic equipment through the oil pressure sensor mounted on the rear of the oil filter module
- The minimum pressure for the engine is 41 kPa (6 psi) at any operating condition
- Anything under this pressure could result in damage to critical moving parts

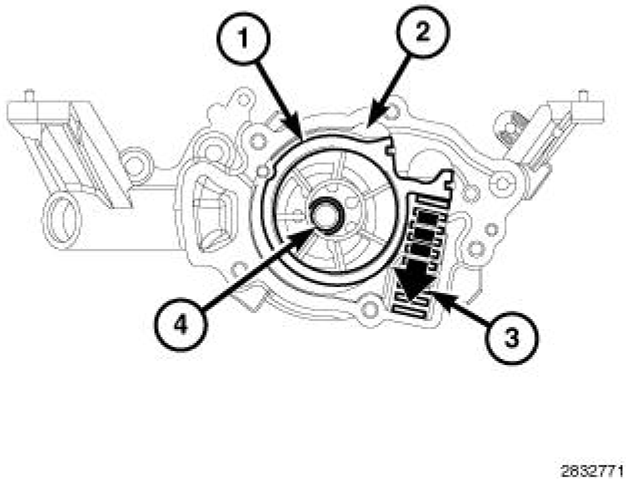


Fig. 527: Moving Element, Main Gallery Oil Pressure, Spring Pressure & Pump Driveshaft
Courtesy of CHRYSLER GROUP, LLC

In high pressure mode regulation (solenoid off) main gallery oil pressure (2) is applied to the moving element (1). The main gallery oil pressure works against spring pressure (3) to move the element to a more concentric location about the pump driveshaft (4) thus reducing displacement and pump output.

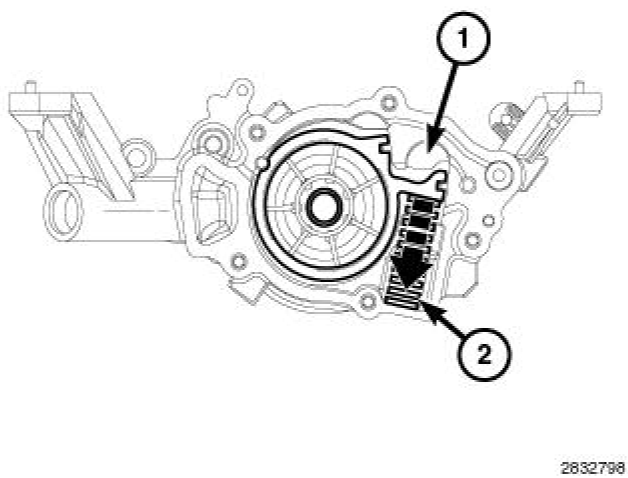

Fig. 528: Chamber & Spring
Courtesy of CHRYSLER GROUP, LLC

In low pressure mode regulation (solenoid on) the energized solenoid opens an additional chamber (1) to main gallery oil pressure increasing the force on the spring (2) to further reduce displacement and output pressure.

NOTE: **The Oil pump is released as an assembly. The assembly includes both the pump and the solenoid. There are no serviceable sub-assembly components. In the event the oil pump or solenoid are not functioning or out of specification they must be replaced as an assembly.**

1. Inspect the solenoid wires (1) for cuts or chafing.
2. Inspect the condition of the connector O-ring seal (3).

INSTALLATION

INSTALLATION

2. Install the oil pump chain tensioner on the oil pump.
3. Position the oil pump chain tensioner spring (1) above the dowel pin (2).
4. Push back the oil pump chain tensioner and insert a suitable retaining pin (3) such as a 3 mm Allen wrench.

NOTE: **There are no timing marks on the oil pump gear or chain. Timing of the oil pump is not required.**

CAUTION: **Always reinstall timing chains so that they maintain the same direction of**

rotation. Inverting a previously run chain on a previously run sprocket will result in excessive wear to both the chain and sprocket.

11. Connect the oil pump solenoid wire harness connector (1).
12. Install the oil pump pick-up. Refer to **PICK-UP, OIL PUMP, INSTALLATION**.
13. If removed, install the oil filter and fill the engine crankcase with the proper oil to the correct level. Refer to **STANDARD PROCEDURE**.
14. Connect the negative battery cable.

CAUTION: A MIL or low oil pressure indicator that remains illuminated for more than 2 seconds may indicate low or no engine oil pressure. Stop the engine and investigate the cause of the indication.

15. Start and run the engine until it reaches normal operating temperature.

SENSOR, OIL PRESSURE

DESCRIPTION

DESCRIPTION

The oil pressure sensor (2) is located on the oil filter housing. The oil pressure sensor is a three wire sensor with a tapered threaded sensor port. The sensor port is mounted to the oil filter housing through an access hole. A thread lock patch seals the oil pressure sensor to the oil filter housing.

OPERATION

OPERATION

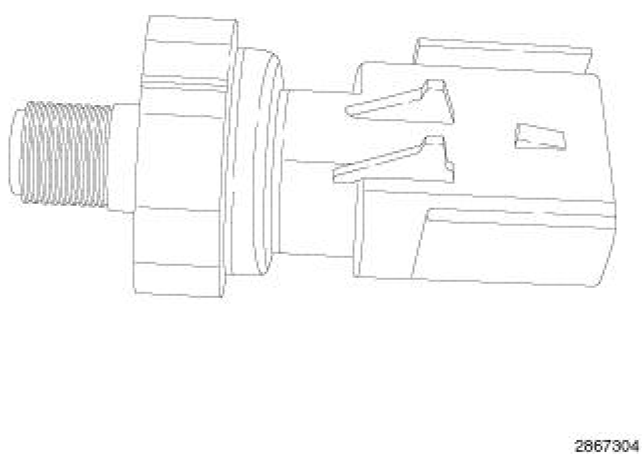

Fig. 546: Oil Pressure Sensor
Courtesy of CHRYSLER GROUP, LLC

The oil pressure sensor is a silicon based sensing unit that measures the pressure of the engine oil. The Powertrain Control Module (PCM) supplies a 5 volt reference and a ground to the sensor. The input to the PCM occurs on the signal return circuit. The oil pressure sensor is a linear sensor; as pressure changes, voltage changes proportionately and returns a voltage signal to the PCM that reflects oil pressure. The zero pressure reading is 0.5 volt and full scale is 4.5 volt.

The oil temperature sensor is a variable resistor that measures the temperature of the engine oil. The Powertrain Control Module (PCM) supplies a 5 volt reference and a ground to the sensors low reference signal circuit. When the oil temperature is low, the sensor resistance is high. When the oil temperature is high, the sensor resistance is low.

MANIFOLDS

MANIFOLD, EXHAUST

DESCRIPTION

DESCRIPTION

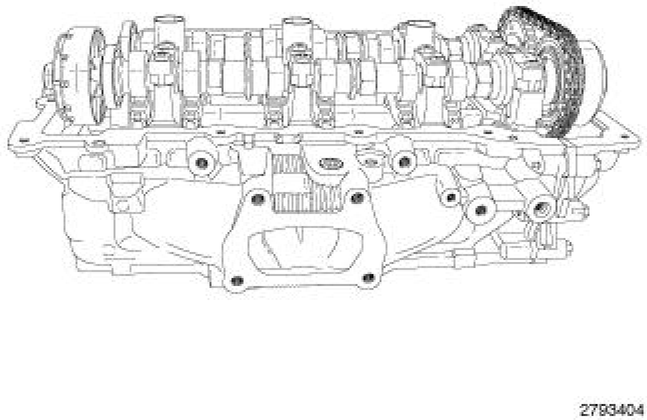

Fig. 553: Aluminum Cylinder Head
Courtesy of CHRYSLER GROUP, LLC

The 3.6L aluminum cylinder heads are a unique design with left and right castings. The exhaust manifolds are integrated into the cylinder heads. If any damaged is found to the exhaust manifold portion, the cylinder head must be removed for repair or replacement. Refer to CYLINDER HEAD, REMOVAL.

MANIFOLD, INTAKE

DESCRIPTION

DESCRIPTION

UPPER INTAKE MANIFOLD

CAUTION: If the engine has experienced a catastrophic failure, THE INTAKE MANIFOLD MUST BE REPLACED!

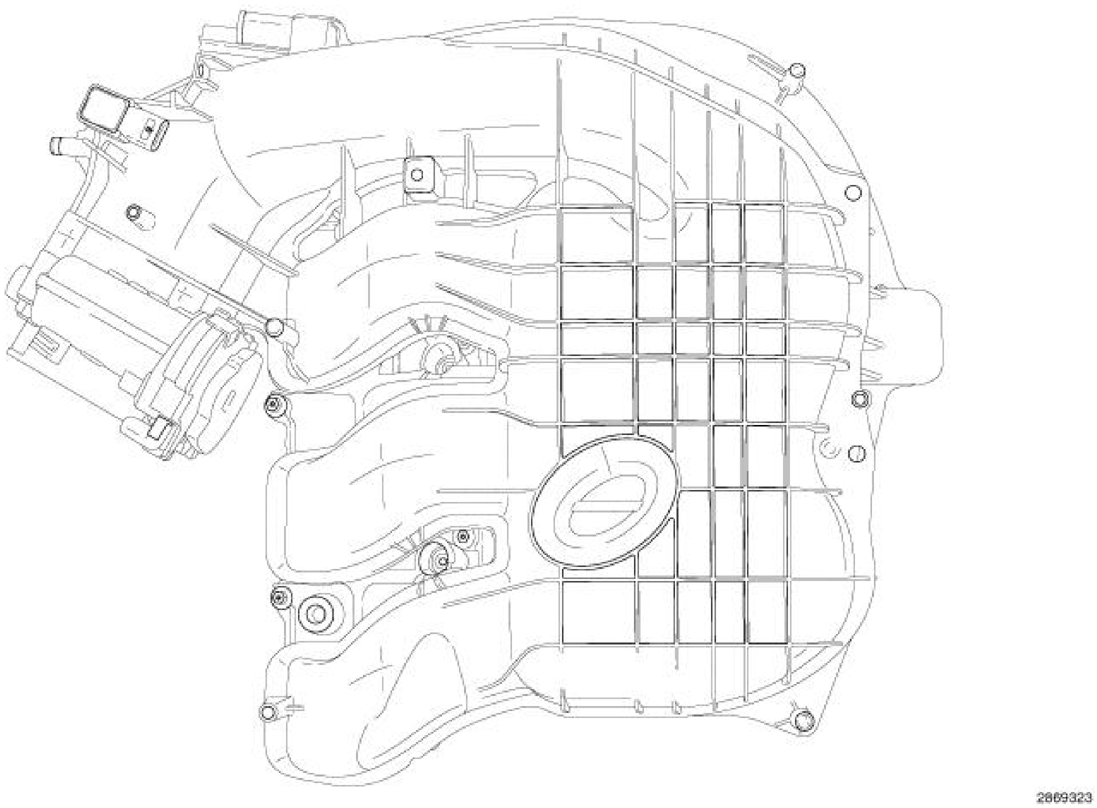

Fig. 554: Upper Intake Manifold Design
Courtesy of CHRYSLER GROUP, LLC

The upper intake manifold is an injection molded nylon composite design:

- The upper intake manifold is sealed to the lower intake manifold using six individual press-in-place port silicone gaskets
- Replace the gaskets whenever the upper intake manifold is removed from the engine
- There is a silencer pad positioned between the upper and lower intake manifolds for improved noise, vibration and harshness (NVH)
- The left cylinder head cover has two alignment posts to aid proper installation of the silencer pad
- The seven upper intake manifold fasteners thread directly into the composite lower intake manifold and are a self-taping design
- If the upper intake manifold is damaged or cracked, it must be replaced
- The Electronic Throttle Control (ETC) and Manifold Air Pressure (MAP) sensor are attached directly to the upper intake manifold
- The upper intake manifold also provides vacuum ports for brake booster, positive crankcase ventilation (PCV) and emissions control

LOWER INTAKE MANIFOLD

CAUTION: If the engine has experienced a catastrophic failure, THE INTAKE MANIFOLD MUST BE REPLACED!

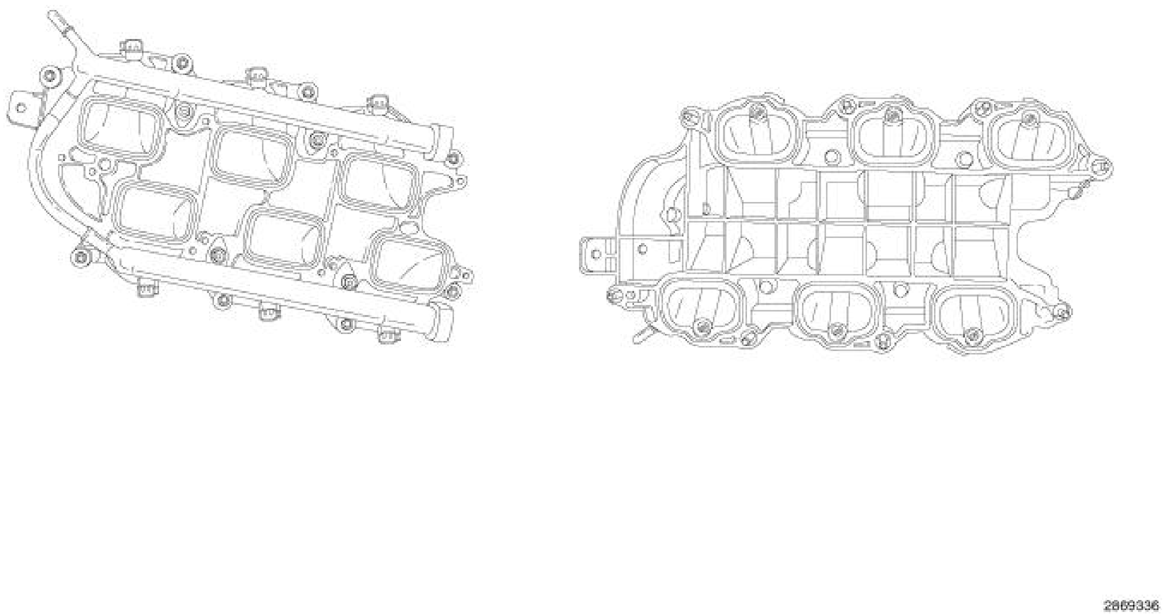

Fig. 555: Lower Intake Manifold Design
Courtesy of CHRYSLER GROUP, LLC

The lower intake manifold is an injection molded nylon composite design:

- The lower intake manifold is sealed to the cylinder heads using six individual press-in-place port silicone gaskets
- Replace the gaskets whenever the lower intake manifold is removed from the engine
- The seven upper intake manifold fasteners thread directly into the composite lower intake manifold and are a self-taping design
- The fuel injection fuel rail is also a composite design
- The four fuel rail fasteners thread directly into the composite lower intake manifold and are a self-taping design
- The lower intake manifold can be serviced without removing the fuel injector rail
- The fuel rail and fuel injectors must be installed into the lower intake manifold as an assembly
- Do not attempt to install the fuel rail when the injectors are in the manifold
- Always install new O-rings on the fuel injectors
- If the lower intake manifold is damaged or cracked, it must be replaced

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - INTAKE MANIFOLD LEAKS

An intake manifold air leak is characterized by lower than normal manifold vacuum. Also, one or more cylinders may not be functioning.

WARNING: Use extreme caution when the engine is operating. Do not stand in a direct line with the fan. Do not put your hands near the pulleys, belts or the fan. Do not wear loose clothing.

1. Start the engine.
2. Spray a small stream of water (spray bottle) at the suspected leak area.
3. If engine RPM'S change, the area of the suspected leak has been found.
4. Repair as required.

REMOVAL

NOTE: **When the upper intake manifold (3) and lower intake manifold (1) are not aligned properly, cross threading of the upper intake manifold attaching bolts can occur. The graphic shows non-repairable damage to the lower intake manifold (1) due to cross threading of an upper intake manifold attaching bolt (2).**

Check both the upper and lower intake manifolds for:

- Damage and cracks
- Gasket surface damage or warping

Check the lower intake manifold for:

- Damaged fuel injector ports

If either the upper or lower manifold exhibits any damaged or warped conditions, replace the manifold.

VALVE TIMING

DESCRIPTION

DESCRIPTION

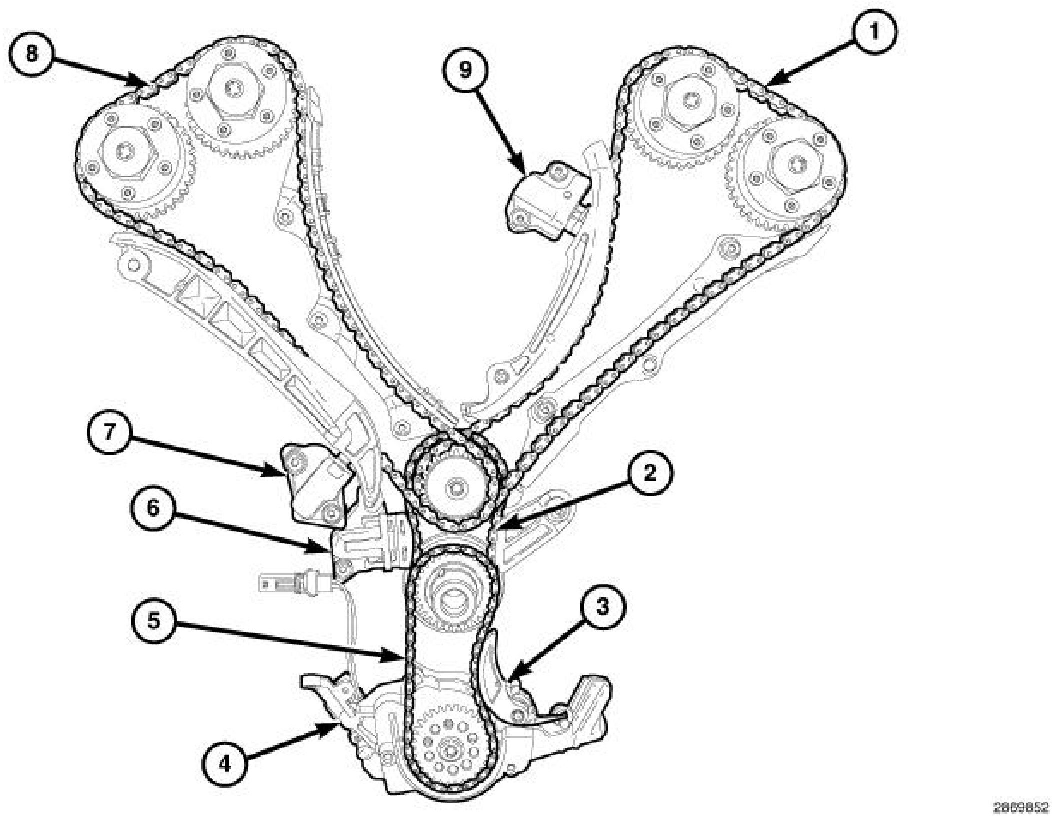

Fig. 593: Valve Timing System Components
Courtesy of CHRYSLER GROUP, LLC

The timing drive uses four silent chains. The silent chain link design improves sprocket engagement and reduces noise, vibration and harshness (NVH). One chain (5) drives the oil pump (4) and three chains drive the camshafts in a two stage design. The left secondary camshaft chain (1) uses an oil pressure controlled chain tensioner (9) with a ratcheting device. The right secondary camshaft chain (8) uses an oil pressure controlled tensioner (7) without a ratchet. The primary chain (2) also uses an oil pressure controlled tensioner (6) without a ratchet. A spring loaded tensioner (3) takes up the slack in the oil pump chain (5). The chain guides and tensioner arms are made of glass filled nylon with nylon wear faces.

OPERATION

OPERATION

Fig. 594: Primary Chain, Idler Sprocket & Crankshaft Sprocket
Courtesy of CHRYSLER GROUP, LLC

The primary timing chain is a silent type. The primary chain drives the 28 tooth idler sprocket directly from a 21 tooth crankshaft sprocket. This results in a 75% speed reduction to the idler sprocket. The idler sprocket assembly connects the primary chain drive and the secondary chain drive. The idler sprocket assembly consists of two integral 22 tooth sprockets a 28 tooth sprocket. The idler sprocket assembly spins on a stationary idler shaft. The idler shaft is a light press-fit into the cylinder block. A large washer on the idler shaft bolt and the rear flange of the idler shaft are used to control sprocket thrust movement. Pressurized oil is routed through the center of the idler shaft to provide lubrication for the bushings used in the idler sprocket assembly. Primary chain motion is controlled by a hydraulic oil damped tensioner and a fixed guide. The tensioner and the guide both use nylon plastic wear faces for low friction and long wear. The primary chain receives oil splash lubrication.

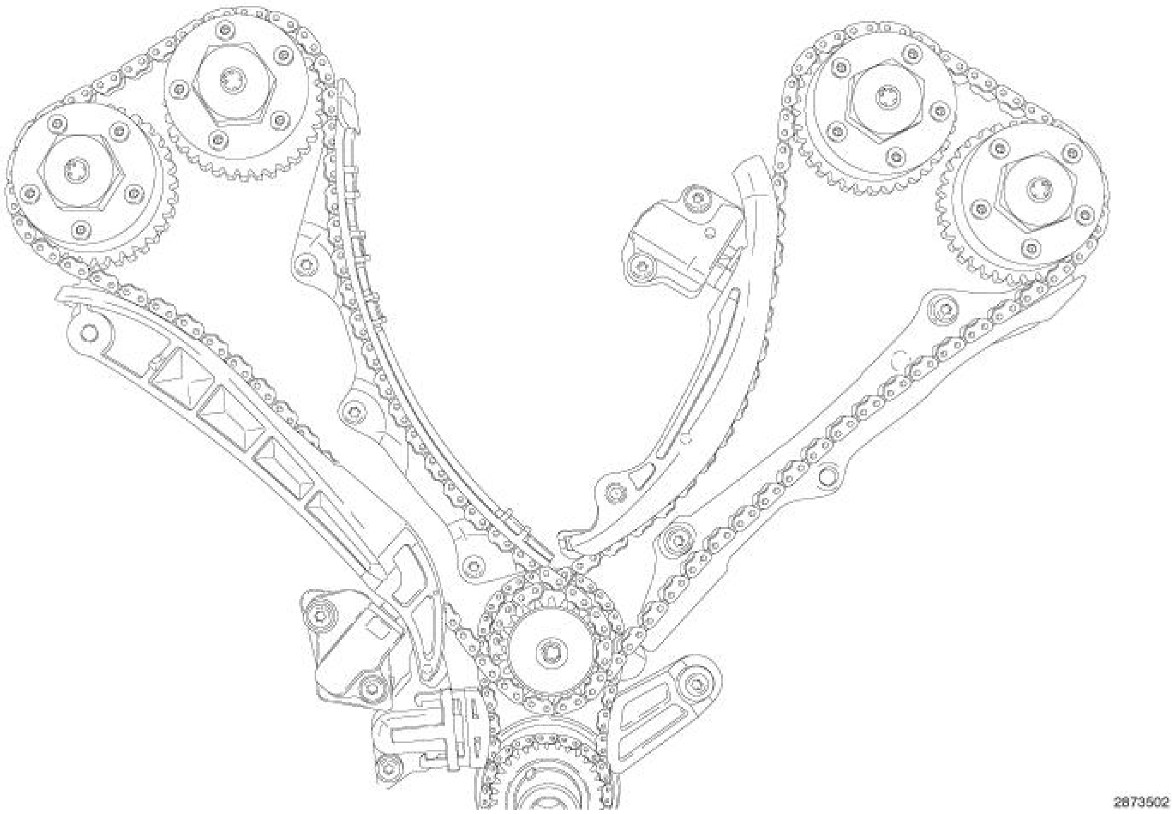

Fig. 595: Secondary Drive Chains
Courtesy of CHRYSLER GROUP, LLC

There are two identical secondary drive chains, both are silent type, one to drive the camshafts in each double overhead cam (DOHC) cylinder head. The secondary chains drive the 33 tooth camshaft sprockets directly from the 22 tooth idler sprockets. This speed reduction combined with the crankshaft to idler sprocket speed reduction produces the required 2:1 camshaft drive ratio. A fixed chain guide and a hydraulic oil damped tensioner are used to maintain tension in each secondary chain system. The left hydraulic secondary chain tensioner is fed from the main oil gallery through the cylinder head. The right hydraulic secondary chain tensioner is fed from the number one main bearing journal. Each tensioner incorporates a controlled leak path through a device known as a vent disc located in the nose of the piston to manage chain loads. Only the left tensioner has a mechanical ratchet system that limits chain slack if the tensioner piston bleeds down after engine shut down. The tensioner arms and guides also utilize nylon wear faces for low friction and long wear. The two secondary timing chains are lubricated by holes in the oil controlled tensioners that spray oil through an opening in the tensioner arms. The holes are protected from clogging by a fine mesh screen which is located on the back of the hydraulic tensioners.

STANDARD PROCEDURE

RESETTING LEFT CAM CHAIN TENSIONER

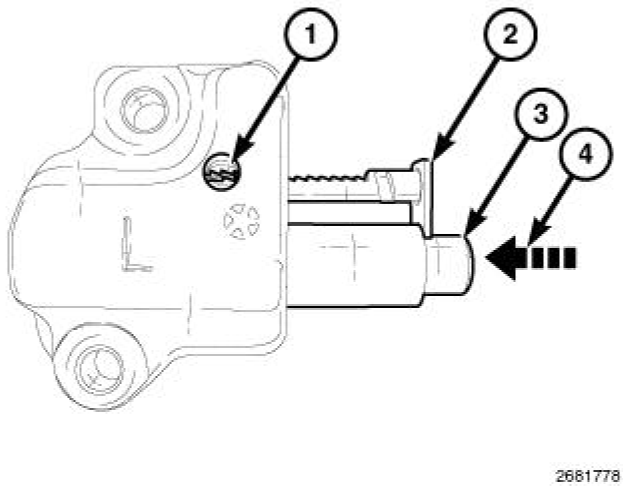

Fig. 596: Left Side Cam Chain Tensioner Ratchet Components
Courtesy of CHRYSLER GROUP, LLC

The left side can chain tensioner used on the 3.6L engine is equipped with a ratchet. The ratchet consists of a rack (2) and a pawl (1). In use, the rack (2) extends with the piston (3) from the tensioner body. The pawl (1) will not allow the rack (2) to retract back into the tensioner body. In order to reset the tensioner, the pawl (1) must be disengaged from the rack (2) so that the piston (3) and rack (2) can be pushed back (4) into the tensioner body.

WITH ENGINE TIMING COVER REMOVED

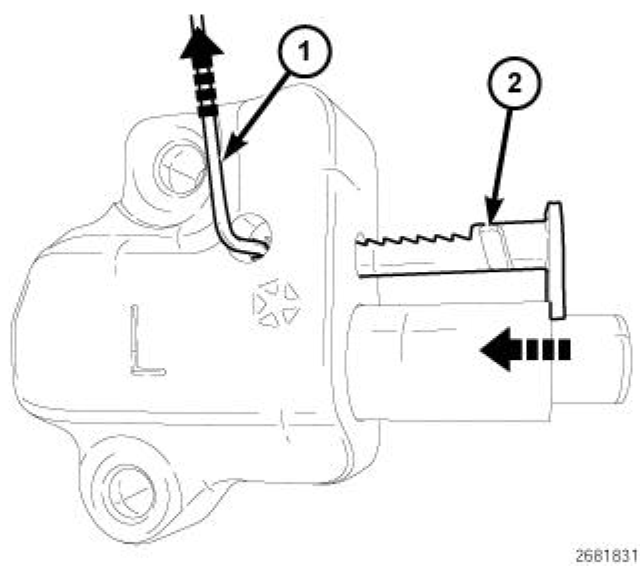

Fig. 597: Locating Slot In Rack & Allen Wrench
Courtesy of CHRYSLER GROUP, LLC

NOTE: **The slot (2) in the rack provides an anchor point for a pin that holds the rack in the retracted position.**

1. Using a suitable tool, such as an Allen wrench (1), lift the pawl off of the rack.
2. While holding the pawl off of the rack, push the rack and the piston into the tensioner body.

3. When the slot is aligned with the hole in the tensioner body, insert Tensioner Pin (special tool #8514, Pins, Tensioner) (1) to hold the rack and piston in the retracted position.

2. While holding the pawl off of the rack, push (special tool #10200-1, Holder, Timing Chain, Left Side) (1) into place between the cylinder head and the cam chain guide to force the rack and piston back into the tensioner body. The holder must remain in place during service to keep the rack and piston in the retracted position.

MEASURING TIMING CHAIN WEAR

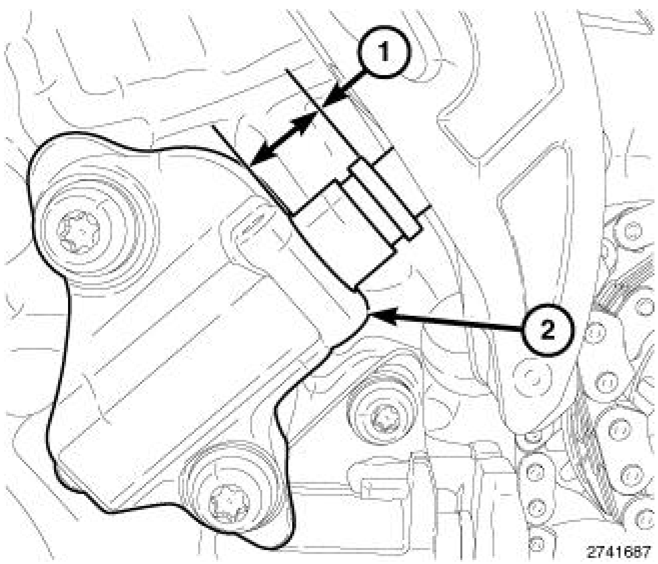

Fig. 601: Piston Extension & Right Hand Cam Chain Tensioner
Courtesy of CHRYSLER GROUP, LLC

1. Remove the engine timing chain cover. Refer to **COVER(S), ENGINE TIMING, REMOVAL**.
2. To determine if the timing chains are worn, rotate the crankshaft clockwise until maximum tensioner piston extension (1) is obtained on the RH cam chain tensioner (2). Measure the distance between the secondary timing chain tensioner housing and the step ledge on the tensioner piston (1). Piston extension (1) must be less than 16 mm (0.630 in.).
3. Piston extension greater than 16 mm (0.630 in.) indicates that all timing chains are worn and require

replacement. Refer to **CHAIN AND SPROCKETS, TIMING, REMOVAL**.

ENGINE TIMING VERIFICATION

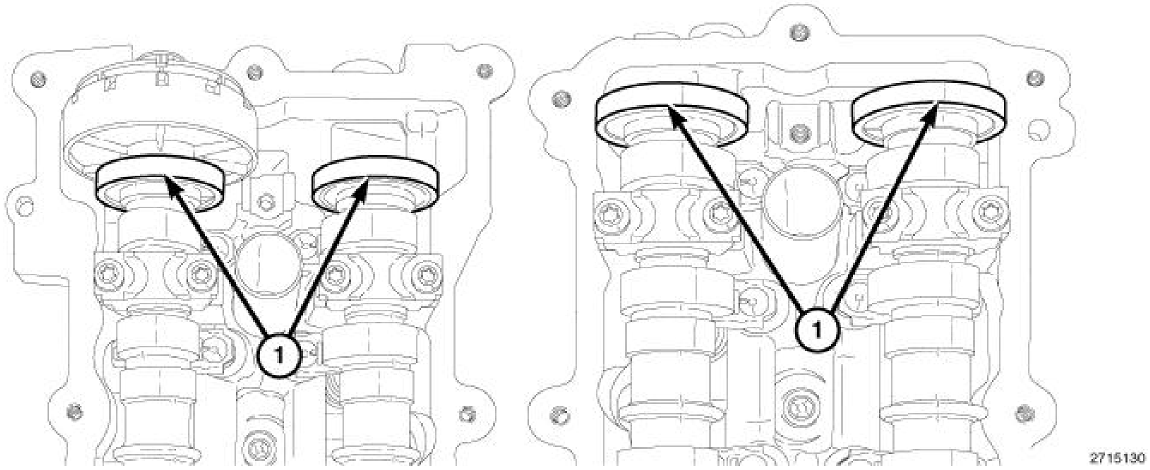

Fig. 602: Magnetic Timing Wheels
Courtesy of CHRYSLER GROUP, LLC

CAUTION: The magnetic timing wheels (1) must not come in contact with magnets (pickup tools, trays, etc.) or any other strong magnetic field. This will destroy the timing wheels ability to correctly relay camshaft position to the camshaft position sensor.

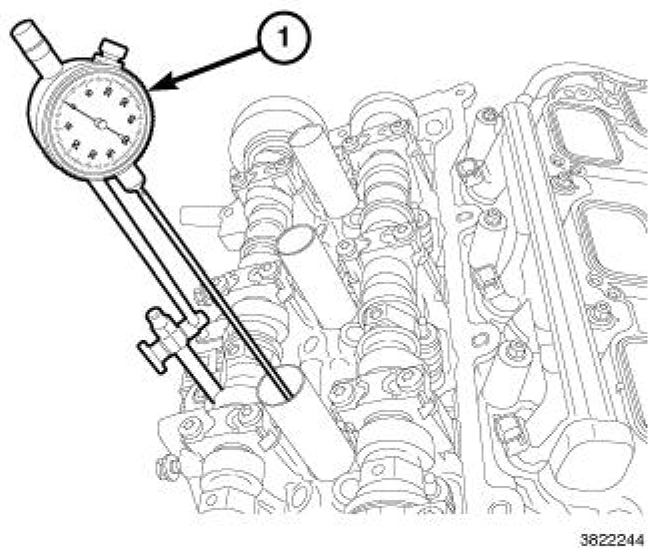

Fig. 603: Mount Dial Indicator Set To Stationary Point On Engine

Correct timing is critical for the NON free-wheeling designed, 3.6L engine. Engine timing can be verified by using the following procedures:

1. Remove the upper intake manifold and both cylinder head covers. Refer to **COVER(S), CYLINDER HEAD, REMOVAL**.
2. Remove the spark plugs. Refer to **SPARK PLUG, REMOVAL** .

CAUTION: When aligning timing marks, always rotate engine by turning the crankshaft. Failure to do so will result in valve and/or piston damage.

3. Mount Dial Indicator Set (special tool #C-3339A, Set, Dial Indicator) (1) to a stationary point on the engine, such as the cylinder head cover mounting surface. Position the indicator probe into the number one cylinder, rotate the crankshaft clockwise (as viewed from the front) to place the number one piston at top-dead-center on the exhaust stroke and set the indicator dial to **ZERO** .

4. While maintaining this alignment, verify that the **ARROWS** (1) on the left side cam phasers point toward each other and are parallel to the cylinder head cover mounting surface (2) and that the right side cam phaser **ARROWS** (3) point away from each other and the **SCRIBE LINES** (5) are parallel to the cylinder head cover mounting surface (4).

NOTE: The phaser markings (1 and 3) could align with either an external or internal chain link. Either alignment is acceptable as long as there are

twelve chain pins between the markings.

5. There should be twelve chain pins (2) **BETWEEN** the exhaust cam phaser triangle marking (1) and the intake cam phaser circle marking (3) as viewed from either the front or rear of the cam phasers.
6. If the engine timing is not correct. Refer to **CHAIN AND SPROCKETS, TIMING, REMOVAL**.

CAUTION: **The magnetic timing wheels (1) must not come in contact with magnets (pickup tools, trays, etc.) or any other strong magnetic field. This will destroy the timing wheels ability to correctly relay camshaft position to the camshaft position sensor.**

CAUTION: **When the timing chains are removed and the cylinder heads are still installed, DO NOT rotate the camshafts or crankshaft without first locating the proper crankshaft position. Failure to do so will result in valve and/or piston damage.**

NOTE: **The Variable Valve Timing (VVT) assemblies (Phasers) and Oil Control Valves (OCVs) can be serviced without removing the engine timing cover. Refer to ASSEMBLY, VARIABLE VALVE TIMING, PHASER/OIL CONTROL VALVE, REMOVAL.**

1. Disconnect and isolate the negative battery cable.
2. Remove the air cleaner body. Refer to **BODY, AIR CLEANER, REMOVAL**.
3. Remove both cylinder head covers. Refer to **COVER(S), CYLINDER HEAD, REMOVAL**.
4. Remove the spark plugs. Refer to **SPARK PLUG, REMOVAL** .
5. Raise and support the vehicle. Refer to **HOISTING, STANDARD PROCEDURE** .
6. Drain the cooling system. Refer to **STANDARD PROCEDURE** .

7. Remove the engine timing cover. Refer to COVER(S), ENGINE TIMING, REMOVAL.

NOTE: **Take this opportunity to measure timing chain wear. Refer to VALVE TIMING, STANDARD PROCEDURE.**

CAUTION: **When aligning timing marks, always rotate engine by turning the crankshaft. Failure to do so will result in valve and/or piston damage.**

8. Rotate the crankshaft clockwise (as viewed from the front) to place the number one cylinder piston at top-dead-center on the exhaust stroke by aligning the dimple (4) on the crankshaft with the block/bearing cap junction (5).
9. While maintaining this alignment, verify that the **ARROWS** (2) on the left side cam phasers point toward each other and are parallel to the cylinder head cover mounting surface (3) and that the right side cam phaser **ARROWS** (7) point away from each other and the **SCRIBE LINES** (9) are parallel to the cylinder head cover mounting surface (8).

NOTE: **The phaser markings (1 and 3) could align with either an external or internal chain link. Either alignment is acceptable as long as there are twelve chain pins between the markings.**

10. There should be twelve chain pins (2) **BETWEEN** the exhaust cam phaser triangle marking (1) and the intake cam phaser circle marking (3) as viewed from either the front or rear of the cam phasers.

CAUTION: **Always reinstall timing chains so that they maintain the same direction of rotation. Inverting a previously run chain on a previously run sprocket will result in excessive wear to both the chain and sprocket.**

11. Mark the direction of rotation on the following timing chains using a paint pen or equivalent to aid in reassembly:
    - Left side cam chain
    - Right side cam chain
    - Oil pump chain
    - Primary chain

36. Inspect all sprockets and chain guides. Replace if damaged.

INSPECTION

INSPECTION

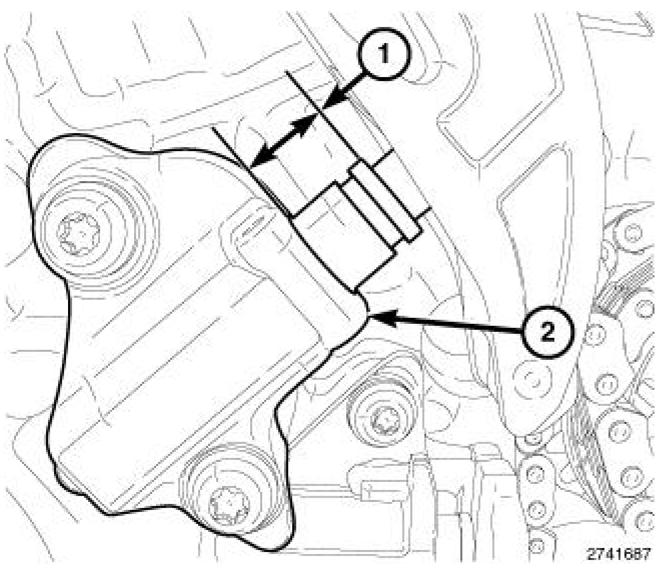

Fig. 618: Piston Extension & Right Hand Cam Chain Tensioner
Courtesy of CHRYSLER GROUP, LLC

Prior to disassembly of the timing chains and sprockets, measure the timing chain wear (1). Refer to **VALVE TIMING, STANDARD PROCEDURE**.

Inspect the following valve timing components:

- Sprockets for excessive tooth wear. Some tooth markings are normal and not a cause for sprocket

replacement.

- Idler sprocket assembly bushing and shaft for excessive wear.
- Chain guides and tensioner arms. Replace these parts if grooving in plastic face is more than 1 mm (0.039 in.) deep.
- Secondary chain tensioner piston and ratcheting device. Inspect for evidence of heavy contact between tensioner piston and tensioner arm. If this condition exist the tensioner arm and chain should be replaced.
- Primary chain tensioner plastic faces. Replace as required.

INSTALLATION

INSTALLATION

1. Inspect all sprockets and chain guides. Replace if damaged.
2. If removed, install the right side cam chain guide (1) and tensioner arm (6). Tighten bolts (2) to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
3. If removed, install the right side cam chain tensioner (3). Tighten bolts (4) to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
4. Reset the right side cam chain tensioner (3) by pushing back the tensioner piston and installing Tensioner Pin (special tool #8514, Pins, Tensioner) (5).

8. Verify that the key (3) is installed in the crankshaft.

CAUTION: **Do not rotate the crankshaft more than a few degrees independently of the camshafts. Piston to valve contact could occur resulting in possible valve damage. If the crankshaft needs to be rotated more than a few degrees, first remove the camshafts.**

9. Verify that the number one cylinder piston is positioned at top-dead-center by aligning the dimple (2) on the crankshaft with the block/bearing cap junction (1).

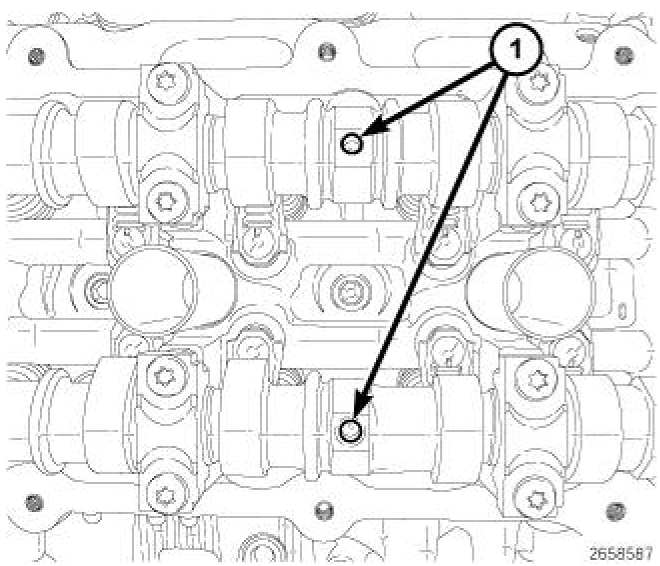

Fig. 623: Positioning Camshaft Alignment Holes Vertically

CAUTION: **Do not rotate the camshafts more than a few degrees independently of the crankshaft. Valve to piston contact could occur resulting in possible valve damage. If the camshafts need to be rotated more than a few degrees, first**

move the pistons away from the cylinder heads by rotating the crankshaft counterclockwise to a position 30Ā° before-top-dead-center. Once the camshafts are returned to their top-dead-center position, rotate the crankshaft clockwise to return the crankshaft to top-dead-center.

10. Verify that the camshafts are set at top-dead-center by positioning the alignment holes (1) vertically.

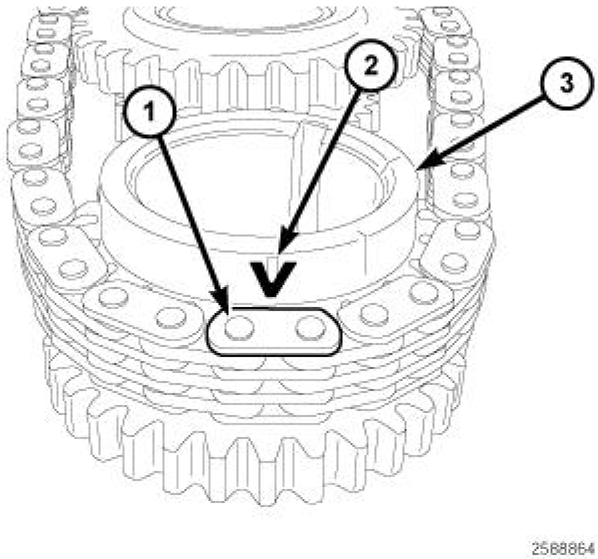

Fig. 624: Aligning Arrow With Plated Link On Primary Chain

CAUTION: Always reinstall timing chains so that they maintain the same direction of rotation. Inverting a previously run chain on a previously run sprocket will result in excessive wear to both the chain and sprocket.

11. Place the primary chain onto the crankshaft sprocket (3) so that the arrow (2) is aligned with the plated link (1) on the timing chain.

13. While maintaining this alignment, lubricate the idler sprocket bushing with clean engine oil and install the sprockets and timing chain on the engine. To verify that the timing is still correct, the timing chain plated link (6) should be located at 12:00 (1) when the dimple (5) on the crankshaft is aligned with the block/bearing cap junction (4).
14. Install the idler sprocket retaining bolt (2) and washer (3). Tighten bolt (2) to the proper specification. Refer to **TORQUE SPECIFICATIONS**.

20. While maintaining this alignment, route the cam chain around the exhaust and intake cam phasers so that the plated links are aligned with the phaser timing marks (1). Position the left side cam phasers so that the arrows (3) point toward each other and are parallel to the cylinder head cover mounting surface (5). Press the exhaust cam phaser onto the exhaust cam, install and hand tighten the oil control valve (2).

NOTE: **Minor rotation of a camshaft (a few degrees) may be required to install the camshaft phaser or phaser lock.**

21. Install the (special tool #10202-2, Lock, Camshaft/Phaser, Left Side) (4) with the tool number facing up.
22. Tighten the oil control valves (2) and (6) to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
23. Remove the Camshaft Phaser Lock (4).

35. There should be 12 chain pins (2) **BETWEEN** the exhaust cam phaser triangle marking (1) and the intake cam phaser circle marking (3) as viewed from either the front or rear of the cam phasers.
36. If the engine timing is not correct, repeat this procedure.
37. Install the engine timing cover. Refer to **COVER(S), ENGINE TIMING, INSTALLATION**.
38. Install the spark plugs. Refer to **SPARK PLUG, INSTALLATION** .
39. Install the cylinder head covers. Refer to **COVER(S), CYLINDER HEAD, INSTALLATION**.
40. Install the air cleaner body. Refer to **BODY, AIR CLEANER, INSTALLATION**.
41. Fill the engine crankcase with the proper oil to the correct level. Refer to **STANDARD PROCEDURE**.
42. Connect the negative battery cable and tighten nut to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
43. Fill the cooling system. Refer to **STANDARD PROCEDURE** .
44. Operate the engine until it reaches normal operating temperature. Check cooling system for correct fluid level. Refer to **STANDARD PROCEDURE** .

NOTE: **The Cam/Crank Variation Relearn procedure must be performed using the scan tool anytime there has been a repair/replacement made to a powertrain system. For example: flywheel, valvetrain, camshaft and/or crankshaft sensors or components.**

4. Clean the engine timing cover, cylinder head and block mating surfaces with isopropyl alcohol in preparation for sealant application. Refer to ENGINE GASKET SURFACE PREPARATION.

CAUTION: **Engine assembly requires the use of a unique sealant that is compatible with engine oil. Using a sealant other than MoparĀ® Threebond Engine RTV Sealant may result in engine fluid leakage.**

CAUTION: **Following the application of MoparĀ® Threebond Engine RTV Sealant to the gasket surfaces, the components must be assembled within 20 minutes and the attaching fasteners must be tightened to specification within 45 minutes. Prolonged exposure to the air prior to assembly may result in engine fluid leakage.**

5. Apply a 2 to 3 mm wide bead of MoparĀ® Threebond Engine RTV Sealant to the front cover as shown in illustration in the following locations:
    - Three cylinder head bosses (1)
    - Right and left flanges (2)
    - Four cylinder head to engine block T-joints (3)
    - Cover to right cam chain tensioner gap (4).

5.7L - Service Information - Challenger

DESCRIPTION

DESCRIPTION

CAUTION: If the engine has experienced a catastrophic failure, THE INTAKE MANIFOLD MUST BE REPLACED!

The 5.7L engine (348 CID) eight-cylinder engine is a 90Â° V-Type lightweight, deep skirt cast iron block, aluminum heads, single cam, overhead valve engine with hydraulic roller tappets. The heads incorporate splayed valves with a hemispherical style combustion chamber and dual spark plugs. The cylinders are numbered from front to rear; 1, 3, 5, 7 on the left bank and 2, 4, 6, 8 on the right bank. The firing order is 1-8-4-3-6-5-7-2.

DIAGNOSIS AND TESTING

PERFORMANCE

CONDITION	POSSIBLE CAUSE	CORRECTION
ENGINE WILL NOT START	1. Weak battery.	1. Charge or replace as necessary.
	2. Corroded or loose battery connections.	2. Clean and tighten battery connections. Apply a coat of light mineral grease to the terminals.
	3. Faulty starter.	3. Refer to **DIAGNOSIS AND TESTING** .
	4. Incorrect spark plug gap.	4. Refer to **SPECIFICATIONS** .
	5. Dirt or water in fuel system.	5. Clean system and replace fuel filter.
	6. Faulty fuel pump, relay or wiring.	6. Refer to **FUEL SYSTEM** article.
ENGINE STALLS OR ROUGH IDLE	1. Idle speed set to low.	1. Refer to **MECHANICAL**.
	2. Vacuum leak.	2. Inspect intake manifold and vacuum hoses, repair or replace as necessary.
ENGINE LOSS OF POWER	1. Dirty or incorrectly gapped spark plugs.	1. Replace spark plugs.
	2. Dirt or water in fuel system.	2. Clean system and replace fuel filter.
	3. Blown cylinder head gasket.	3. Replace cylinder head gasket.
	4. Low compression.	4. Refer to **CYLINDER COMPRESSION TEST**.

CONDITION	POSSIBLE CAUSE	CORRECTION
	5. Burned, warped or pitted valves.	5. Replace as necessary.
	6. Plugged or restricted exhaust system.	6. Inspect and replace as necessary.

CYLINDER LEAKAGE TEST

The cylinder leakage test provides an accurate means for determining engine condition.

Cylinder leakage testing will detect:

- Exhaust and intake valve leaks (improper seating).
- Leaks between adjacent cylinders or into water jacket.

1. Check the coolant level and fill as required. DO NOT install the radiator cap.
2. Start and operate the engine until it attains normal operating temperature.
3. Turn the engine OFF.
4. Remove the spark plug from the cylinder being tested.
5. Remove the oil filler cap.
6. Remove the air cleaner hose.
7. **Calibrate the tester according to the manufacturer's instructions.** The shop air source for testing should maintain a regulated air pressure at 552 kPa (80 psi).
8. Perform the test procedures on each cylinder according to the tester manufacturer's instructions. Set the piston of the cylinder to be tested at TDC compression.
9. During the testing, listen for pressurized air escaping through the throttle body, tailpipe and oil filler cap opening. Check for bubbles in the radiator coolant.

All gauge pressure indications should be equal, with **no more** than 25% leakage.

FOR EXAMPLE: Input air at 552 kPa (80 psi), the primary gauge factory set at 207 kPa (30 psi) input pressure. The secondary gauge should have no more than 176 kPa (25.5 psi) loss, when connected to the cylinder.

Refer to CYLINDER LEAK TEST DIAGNOSIS CHART.

CYLINDER LEAKAGE TEST DIAGNOSIS CHART

CONDITION	POSSIBLE CAUSE	CORRECTION
AIR ESCAPES THROUGH THROTTLE BODY	Intake valve bent, burnt, or not seated properly	Inspect valve and valve seat. Reface or replace, as necessary. Inspect valve springs. Replace as necessary.
AIR ESCAPES THROUGH TAILPIPE	Exhaust valve bent, burnt, or not seated properly	Inspect valve and valve seat. Reface or replace, as necessary. Inspect valve springs. Replace as necessary.
AIR ESCAPES THROUGH RADIATOR	Head gasket leaking or cracked cylinder head or block	Remove cylinder head and inspect. Replace defective part.

CONDITION	POSSIBLE CAUSE	CORRECTION
MORE THAN 50% LEAKAGE FROM ADJACENT CYLINDERS	Head gasket leaking or crack in cylinder head or block between adjacent cylinders	Remove cylinder head and inspect. Replace gasket, head, or block as necessary.
MORE THAN 25% LEAKAGE AND AIR ESCAPES THROUGH OIL FILLER CAP OPENING ONLY	Stuck or broken piston rings; cracked piston; worn rings and/or cylinder wall	Inspect for broken rings or piston. Measure ring gap and cylinder diameter, taper and out-of-round. Replace defective part as necessary.

CYLINDER COMPRESSION TEST

NOTE: The results of a cylinder compression pressure test can be utilized to diagnose several engine malfunctions.

NOTE: Be certain the battery is completely charged and the engine starter motor is in good operating condition. Otherwise the indicated compression pressures may not be valid for diagnosis purposes.

1. Clean the spark plug recesses with compressed air.
2. Remove the spark plug from the cylinder being tested and record the cylinder number of each spark plug for future reference.
3. Inspect the spark plug electrodes for abnormal firing indicators such as fouled, hot, oily, etc.
4. Disable the fuel system and perform the fuel system pressure release procedure. Refer to FUEL DELIVERY, GAS, STANDARD PROCEDURE .
5. Insert a compression pressure gauge and rotate the engine with the engine starter motor for three revolutions.
6. Record the compression pressure on the third revolution. Continue the test for the remaining cylinders.

   NOTE: The recommended compression pressures are to be used only as a guide to diagnosing engine problems. An engine should not be disassembled to determine the cause of low compression unless some malfunction is present.

7. Compression should not be less than 689 kPa (100 psi) and not vary more than 25 percent from cylinder to cylinder.
8. If one or more cylinders have abnormally low compression pressures, repeat the compression test.

   NOTE: If the same cylinder or cylinders repeat an abnormally low reading on the second compression test, it could indicate the existence of a problem in the cylinder in question.

9. If one or more cylinders continue to have abnormally low compression pressures, perform the cylinder combustion pressure leakage test. Refer to CYLINDER LEAKAGE TEST.

	4. Scuffed pistons/cylinder walls.	4. Hone the cylinder bores and replace pistons as required. Refer to **ROD, PISTON AND CONNECTING, REMOVAL, 5.7L**.
	5. Carbon in oil control ring groove.	5. Remove the rings and de-carbon the piston. Refer to **STANDARD PROCEDURE**.
	6. Worn valve guides.	6. Inspect the valve guides for wear, cracks or looseness. If either condition exist, replace the cylinder head.
	7. Piston rings fitted too tightly in grooves.	7. Remove the rings and check the ring end gap and side clearance. Replace if necessary. Refer to **STANDARD PROCEDURE**.

Lifter Purge Guideline

1. Warm engine to standard idle conditions.

NOTE: Engine noise may be in the form of a clicking, chatter, or clattering noise.

2. Listen to the engine for 30 to 60 seconds with the hood up and the engine cover removed.
3. If noise is present, de-aeration of the lifters is required.
4. Run the engine between 2000 and 3000 RPM for three to five minutes.
5. Return the engine to standard idle speed for 30 to 60 seconds.
6. Evaluate noise. If noise is present, repeat the run an additional 4 cycles.

NOTE: The standard drive cycle will be about 10 - 15 miles of non- stop, combined highway and city driving.

7. If noise is present, take the vehicle on a standard drive cycle.

NOTE: Use a feeler gauge to verify clearance is present between the lifter and cam base circle.

8. Evaluate the noise. If noise present, follow standard service procedure for lifter repairs or noise conditions.
9. Evaluate lifters for sponginess, check valve defects, and clearance.

OIL CONSUMPTION TEST AND DIAGNOSIS

The following diagnostic procedures are used to determine the source of excessive internal oil consumption, these procedures and tests apply to vehicles with 50, 000 miles or less.

NOTE: Engine oil consumption may be greater than normal during engine break-in. Repairs should be delayed until vehicle has been driven at least 7, 500 miles.

Severe service (high ambient temperature, short trips, heavy loading, trailer towing, taxi, off-road, or law enforcement use) may result in greater oil consumption than normal.

Sustained high speed driving and high engine RPM operation may result in increased oil consumption.

Failure to comply with the recommended oil type and viscosity rating, as outlined in the owner's manual, may impact oil economy as well as fuel economy.

Oil consumption may increase with vehicle age and mileage due to normal engine wear.

NOTE: Because a few drops of external oil leakage per mile can quickly account for the loss of one quart of oil in a few hundred miles, verify that no external engine oil leaks are present.

- **Oil leakage is not the same as oil consumption and all external leakage must be eliminated before any action can be taken to verify and correct oil consumption complaints.**
- **Verify that the engine has the correct oil level dipstick and dipstick tube installed.**
- **Verify that the engine is not being run in an overfilled condition. Check the oil level 15 minutes after a hot shutdown with the vehicle parked on a level surface. In no case should the level be above MAX or the FULL mark on the dipstick.**

OIL CONSUMPTION TEST

1. Check the oil level at least 15 minutes after a hot shutdown.
2. If the oil level is low, top off with the proper viscosity and API service level engine oil. Add one bottle of MOPARĀ® 4-In-1 Leak Detection Dye into the engine oil.
3. Tamper proof the oil pan drain plug, oil filter, dipstick and oil fill cap.
4. Record the vehicle mileage.
5. Instruct the customer to drive the vehicle as usual.
6. Ask the customer to return to the servicing dealer after accumulating 500 miles, Check the oil level at least 15 minutes after a hot shutdown. If the oil level is half way between the "FULL" and "ADD" mark continue with the next step.
7. Using a black light, recheck for any external engine oil leaks, repair as necessary, if no external engine oil leaks are present, continue with oil consumption diagnosis.

OIL CONSUMPTION DIAGNOSIS

1. Check the Positive Crankcase Ventilation (PCV) system. Make sure the system is not restricted and the PCV valve has the correct part number and correct vacuum source (18-20 in. Hg at idle below 3000 ft. above sea level is considered normal).
2. Perform a cylinder compression test and cylinder leak down test using the standard leak down gauge following manufacturers suggested best practices. Refer to **CYLINDER COMPRESSION TEST** and **CYLINDER LEAKAGE TEST**.

NOTE: **Verify the spark plugs are not oil saturated. If the spark plugs are oil saturated and compression is good it can be assumed the valve seals or valve guides are at fault.**

3. If one or more cylinders have more than 15% leak down further engine tear down and inspection will be required.

TOP 18 REASONS THAT MAY LEAD TO ENGINE OIL CONSUMPTION

1. **Tapered and Out-of-Round Cylinders**

   The increased piston clearances permit the pistons to rock in the worn cylinders. While tilted momentarily, an abnormally large volume of oil is permitted to enter on one side of the piston. The rings, also tilted in the cylinder, permit oil to enter on one side. Upon reversal of the piston on each stroke, some of this oil is passed into the combustion chamber.

2. **Distorted Cylinders**

   This may be caused by unequal heat distribution or unequal tightening of cylinder head bolts. This condition presents a surface which the rings may not be able to follow completely. In this case, there may be areas where the rings will not remove all of the excess oil. When combustion takes place, this oil will be burned and cause high oil consumption.

3. **Improper operation of the PCV system**

   The main purpose of the Positive Crankcase Ventilation (PCV) valve is to recirculate blow-by gases back from the crankcase area through the engine to consume unburned hydrocarbons. The PCV system usually has a one way check valve and a make up air source. The system uses rubber hoses that route crankcase blow by gases to the intake manifold. Vacuum within the engine intake manifold pulls the blow by gases out of the crankcase into the combustion chamber along with the regular intake air and fuel mixture.

   The PCV system can become clogged with sludge and varnish deposits and trap blow by gases in the crankcase. This degrades the oil, promoting additional formation of deposit material. If left uncorrected, the result is plugged oil rings, oil consumption, rapid ring wear due to sludge buildup, ruptured gaskets and seals due to crankcase pressurization.

4. **Worn Piston Ring Grooves**

   For piston rings to form a good seal, the sides of the ring grooves must be true and flat - not flared or shouldered. Piston rings in tapered or irregular grooves will not seal properly and, consequently, oil will pass around behind the rings into the combustion chamber.

5. **Worn, Broken or Stuck Piston Rings**

When piston rings are broken, worn or stuck to such an extent that the correct tension and clearances are not maintained, this will allow oil to be drawn into the combustion chamber on the intake stroke and hot gases of combustion to be blown down the cylinder past the piston on the power stroke. All of these conditions will result in burning and carbon build up of the oil on the cylinders, pistons and rings.

6. **Cracked or Broken Ring Lands**

   Cracked or broken ring lands prevent the rings from seating completely on their sides and cause oil pumping. This condition will lead to serious damage to the cylinders as well as complete destruction of the pistons and rings. Cracked or broken ring lands cannot be corrected by any means other than piston replacement.

7. **Worn Valve Stems and Guides**

   When wear has taken place on valve stems and valve guides, the vacuum in the intake manifold will draw oil and oil vapor between the intake valve stems and guides into the intake manifold and then into the cylinder where it will be burned.

8. **Bent or Misaligned Connecting Rods**

   Bent or misaligned connecting rods will not allow the pistons to ride straight in the cylinders. This will prevent the pistons and rings from forming a proper seal with the cylinder walls and promote oil consumption. In addition, it is possible that a bearing in a bent connect rod will not have uniform clearance on the connecting rod wrist pin. Under these conditions, the bearing will wear rapidly and throw off an excessive amount of oil into the cylinder.

9. **Fuel Dilution**

   If raw fuel is allowed to enter the lubrication system, the oil will become thinner and more volatile and will result in higher oil consumption. The following conditions will lead to higher oil consumption;

   - Excess fuel can enter and mix with the oil via a leaking fuel injector
   - Gasoline contaminated with diesel fuel
   - Restricted air intake
   - Excessive idling

10. **Contaminated Cooling Systems**

    Corrosion, rust, scale, sediment or other formations in the water jacket and radiator will prevent a cooling system from extracting heat efficiently. This is likely to cause cylinder distortion thus leading to higher oil consumption.

11. **Oil Viscosity**

    The use of oil with a viscosity that is too light may result in high oil consumption. Refer to the vehicle owner's manual for the proper oil viscosity to be used under specific driving conditions and ambient temperatures.

12. **Dirty Engine Oil**

Failure to change the oil and filter at proper intervals may cause the oil to be so dirty that it will promote accumulation of sludge and varnish and restrict oil passages in the piston rings and pistons. This will increase oil consumption; dirty oil by nature is also consumed at a higher rate than clean oil.

13. **Crankcase Overfull**

   Due to an error in inserting the oil dip stick so that it does not come to a seat on its shoulder, a low reading may be obtained. Additional oil may be added to make the reading appear normal with the stick in this incorrect position which will actually make the oil level too high. If the oil level is so high that the lower ends of the connecting rods touch the oil in the oil pan excessive quantities of oil will be thrown on the cylinder walls and some of it will work its way up into the combustion chamber.

14. **Excessively High Oil Pressure**

   A faulty oil pressure relief valve may cause the oil pressure to be too high. The result will be that the engine will be flooded with an abnormally large amount of oil in a manner similar to that which occurs with worn bearings. This condition may also cause the oil filter to burst.

15. **Aftermarket Performance Chips and Modification**

   Increasing performance through the use of performance/power enhancement products to a stock or factory engine will increase the chance of excessive oil consumption.

16. **Lugging Engine**

   Lugging is running the engine at a lower RPM in a condition where a higher RPM (more power/torque) should be implemented. Especially susceptible on vehicles equipped with a manual transmission. This driving habit causes more stress loading on the piston and can lead to increases in engine oil consumption.

17. **Turbocharged Engines**

   There is a possibility for PCV "push-over" due to higher crankcase pressure (as compared to naturally aspirated engines) which is normal for turbocharged engines. This condition causes varying amounts of engine oil to enter the intake manifold, charge air cooler and associated plumbing to and from the charge air cooler, also a leaking turbocharger seal will draw oil into the combustion chamber where it will burn (blue smoke from the tail pipe may be present) and form carbon deposits which contribute to further oil consumption as they interfere with proper engine function.

18. **Restricted Air Intake**

   Excessive restriction in the air intake system will increase engine vacuum and can increase oil consumption. An extremely dirty air filter would be one example of this situation.

STANDARD PROCEDURE

DUST COVERS AND CAPS

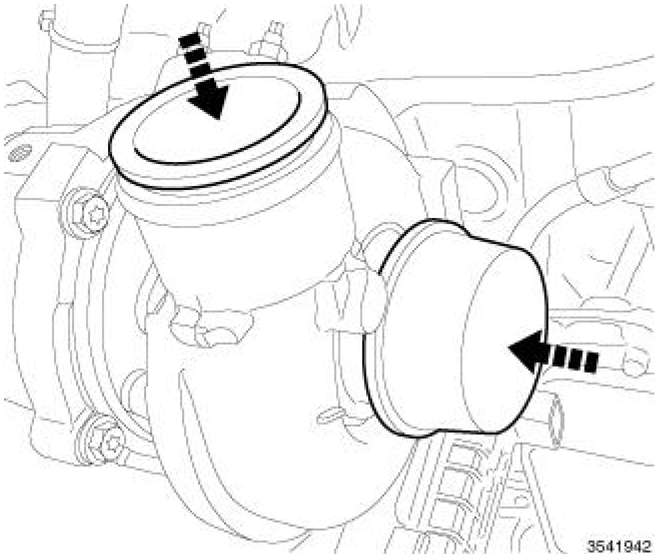

Fig. 1: Covers/Caps
Courtesy of CHRYSLER GROUP, LLC

To avoid the possibility of dust, dirt, moisture and other foreign debris being introduced to the engine during service, cover or cap all openings when hoses and tubes are removed.

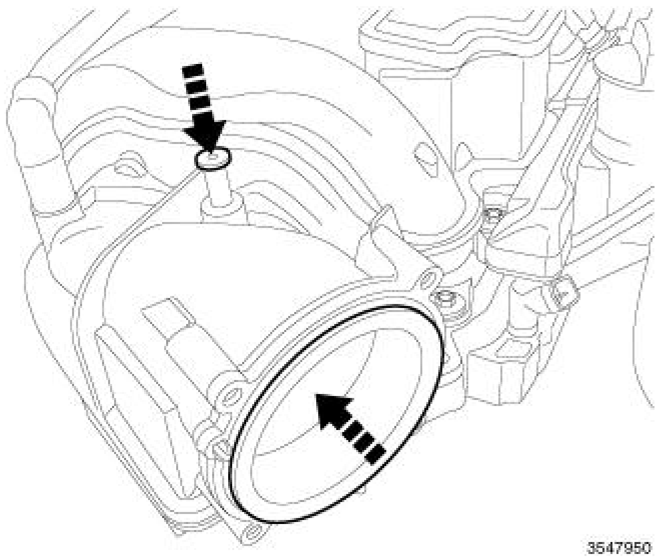

Fig. 2: Opening Cover
Courtesy of CHRYSLER GROUP, LLC

Covers installed over openings will reduce the possibility of foreign materials to entering the engine systems. Using miller tool Universal Protective Cap Set (special tool #10368, Set, Universal Protective Cap), select the appropriate cover needed for the procedure.

ENGINE GASKET SURFACE PREPARATION

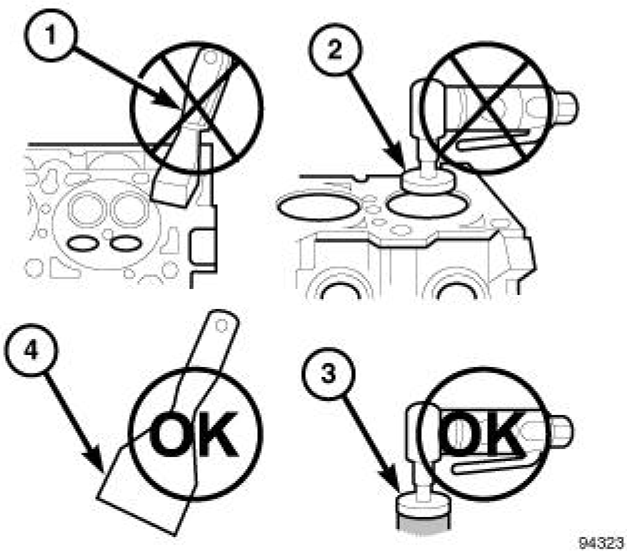

Fig. 3: Proper Tool Usage For Surface Preparation
Courtesy of CHRYSLER GROUP, LLC

To ensure engine gasket sealing, proper surface preparation must be performed, especially with the use of aluminum engine components and multi-layer steel cylinder head gaskets.

Never use the following to clean gasket surfaces:

- Metal scraper (1).
- Abrasive pad or paper to clean cylinder block and head.
- High speed power tool with an abrasive pad or a wire brush (2).

NOTE: **Multi-Layer Steel (MLS) head gaskets require a scratch free sealing surface.**

Only use the following for cleaning gasket surfaces:

- Solvent or a commercially available gasket remover
- Plastic or wood scraper (4).
- Drill motor with 3M Roloc™ Bristle Disc (3), white is used for the aluminum heads and yellow is used for the iron block.

CAUTION: **Excessive pressure or high RPM (beyond the recommended speed), can damage the sealing surfaces. The mild (white, 120 grit) bristle disc is recommended. If necessary, the medium (yellow, 80 grit) bristle disc may be used on cast iron surfaces with care.**

DUST COVERS AND CAPS

Covers installed over openings will reduce the possibility of foreign materials to entering the engine systems. Using miller tool Universal Protective Cap Set (special tool #10368, Set, Universal Protective Cap), select the appropriate cover needed for the procedure.

REPAIR DAMAGED OR WORN THREADS

CAUTION: Be sure that the tapped holes maintain the original center line.

Damaged or worn threads can be repaired. Essentially, this repair consists of:

- Drilling out worn or damaged threads.

- Tapping the hole with a special Heli-Coil Tap.
- Installing an insert into the tapped hole to bring the hole back to its original thread size.

HYDROSTATIC LOCK

CAUTION: Do not attempt to run engine. Severe damage could occur.

When an engine is suspected of hydrostatic lock (regardless of what caused the problem), follow the steps below.

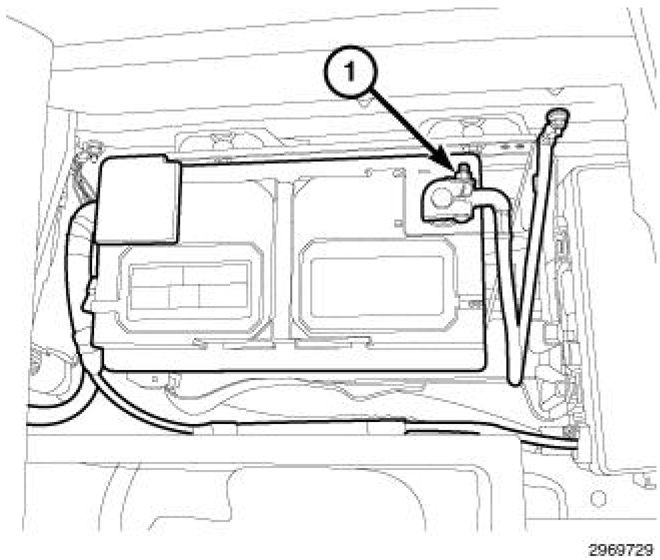

Fig. 6: Negative Battery Cable

2. Lift the engine cover retaining grommets off the ball studs and remove the engine cover (2).

3. Place a shop towel around the fuel supply line Quick Connect Fitting to catch any fuel that may be under pressure and disconnect the fuel supply line. Refer to **FITTING, QUICK CONNECT, STANDARD PROCEDURE** .

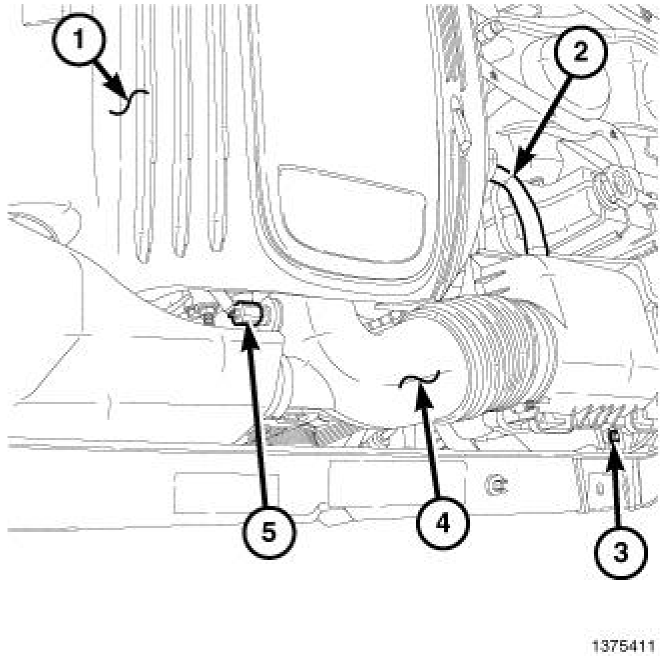

Fig. 8: Air Filter Assembly
Courtesy of CHRYSLER GROUP, LLC

4. Disconnect the Intake Air Temperature (IAT) sensor wire harness connector (5).
5. Loosen the air duct retaining clamps at the throttle body and the air cleaner housing and remove the air duct (4).
6. Disconnect the Make Up Air hose (MUA) (2).
7. Remove the air cleaner housing retaining bolt (3).
8. Remove the air cleaner housing from the vehicle.
9. Inspect the air duct, air cleaner housing and the intake manifold to make sure the system is dry and clear of any foreign material.
10. Place a shop towel around the spark plugs to catch any fluid that may possibly be under pressure in the cylinder head.
11. Remove the spark plugs. Refer to **SPARK PLUG, REMOVAL** .
12. With the spark plugs removed, rotate the crankshaft using a breaker bar and socket.
13. Identify the fluid in the cylinders (coolant, fuel, oil).
14. Make sure all fluid has been removed from the cylinders.
15. Repair engine or components as necessary to prevent this problem from occurring again.
16. Squirt a small amount of engine oil into the cylinders to lubricate the walls. This will help prevent engine damage on restart.
17. Install new spark plugs. Refer to **SPARK PLUG, INSTALLATION** .
18. Perform the Engine Oil Service procedure. Refer to **STANDARD PROCEDURE**.
19. Connect the negative battery cable.

20. Start the engine and check for leaks.

FORM-IN-PLACE GASKETS AND SEALERS

NOTE: All sealants mentioned below are not used on every engine; they are listed as general reference guide. See service information for specific sealer usage.

There are numerous places where form-in-place gaskets are used on the engine. Care must be taken when applying form-in-place gaskets to assure obtaining the desired results.**Do not use form-in-place gasket material unless specified.** Bead size, continuity, and location are of great importance. Too thin of a bead can result in leakage while too much can result in spill-over which can break off and obstruct fluid feed lines. A continuous bead of the proper width is essential to obtain a leak-free gasket. All sealing surfaces that use form-in-place gaskets and sealers must be free of grease or oil. Clean surfaces with MoparĀ® brake parts cleaner prior to sealer application. After the sealer is applied, assemble the parts.

Numerous types of form-in-place gasket materials are used in the engine area. MoparĀ® Sealant RTV Silicone Rubber Adhesive, MOPARĀ® Silicone Rubber RTV, MoparĀ® ATF-RTV and MoparĀ® Gasket Maker gasket materials, each have different properties and cannot be used in place of the other.

MOPARĀ® SEALANT RTV SILICONE RUBBER ADHESIVE is used to seal components exposed to engine oil. This material is a specially designed black silicone rubber RTV that retains adhesion and sealing properties when exposed to engine oil. Moisture in the air causes the material to cure. This material is available in three ounce tubes and has a shelf life of one year. After one year this material will not properly cure. Always inspect the package for the expiration date before use.

MOPARĀ® SILICONE RUBBER RTV is used to seal components exposed to engine oil, gear lubricant, and coolant. This material is a specially designed gray silicone rubber RTV that retains adhesion and sealing properties when exposed to engine oil, gear lubricant and coolant. Excellent adhesion even on oily surfaces, withstands temperatures to 330Ā° C (626Ā° F). Moisture in the air causes the material to cure. This material is available in three ounce tubes and has a shelf life of one year. After one year this material will not properly cure. Always inspect the package for the expiration date before use.

MOPARĀ® ATF-RTV is a specially designed black silicone rubber RTV that retains adhesion and sealing properties to seal components exposed to automatic transmission fluid, engine coolants, and moisture. This material is available in three ounce tubes and has a shelf life of one year. After one year this material will not properly cure. Always inspect the package for the expiration date before use.

MOPARĀ® GASKET MAKER is an anaerobic type gasket material. The material cures in the absence of air when squeezed between two metallic surfaces. It will not cure if left in the uncovered tube. The anaerobic material is for use between two machined surfaces. Do not use on flexible metal flanges.

MOPARĀ® GASKET SEALANT is a slow drying, permanently soft sealer. This material is recommended for sealing threaded fittings and gaskets against leakage of oil and coolant. It can be used on threaded and machined parts under all temperatures. This material also prevents corrosion. MoparĀ® Gasket Sealant is available in a 13 oz. aerosol can or in a 4 oz. or 6 oz. can with applicator.

SEALER APPLICATION

Apply 1 mm (0.040 in.) diameter or less of MoparĀ® Gasket Maker material to one gasket surface. Be certain the material surrounds each mounting hole. Excess material can easily be wiped off. Tighten the components in

place while the sealant is still wet to the touch. Use a locating dowel during assembly to prevent smearing material off the location.

Apply MoparÃ® RTV or ATF-RTV gasket material in a continuous bead approximately 3 mm (0.120 in.) in diameter. For corner sealing and "T-Joint" locations and waffle pad area, a 0.635 mm (0.025 in.) drop is placed in the center of the gasket contact area. Remove uncured sealant with a shop towel. Tighten the components in place while the sealant is still wet to the touch. Use a locating dowel during assembly to prevent smearing material off the location.

REMOVAL

REMOVAL

CAUTION: If the original engine has experienced a catastrophic failure or an individual failure with the piston, cylinder bore, engine block, valve or valve seat, the intake manifold MUST be replaced with a new manifold.

1. Remove the hood. Refer to HOOD, REMOVAL .
2. Remove the cowl panel cover. Refer to COVER, COWL PANEL, REMOVAL .

4. Lift the engine cover retaining grommets off the ball studs and remove the engine cover (2).
5. Perform the fuel system pressure release procedure. Refer to **FUEL DELIVERY, GAS, STANDARD PROCEDURE** .
6. Disconnect and isolate the negative battery cable.

NOTE: **Remove the intake manifold and throttle body as an assembly.**

7. Remove the intake manifold. Refer to **MANIFOLD, INTAKE, REMOVAL, 5.7L**.

NOTE: **The engine must be at room temperature before removing the oil control valve.**

8. Disconnect the oil control valve wire harness connector (1).
9. Remove the oil control valve retaining bolt (2).
10. Rotate the oil control valve (3) to break the seal then pull the oil control valve straight out.
11. Remove the cooling fan. Refer to **FAN, COOLING, REMOVAL** .

12. Raise and support the vehicle. Refer to **HOISTING, STANDARD PROCEDURE** .
13. Remove bolts (1) and the belly pan.
14. Drain the cooling system. Refer to **STANDARD PROCEDURE** .
15. Drain the engine oil. Refer to **STANDARD PROCEDURE**.
16. Remove the A/C compressor. Refer to **COMPRESSOR, A/C, REMOVAL** .

NOTE: **Two knock sensors are used. Each sensor is bolted to the outside of the engine block below the exhaust manifold.**

NOTE: **Left side shown in illustration, right side similar.**

21. Remove the heat shields from both knock sensors (shield snaps on/off sensor).
22. Disconnect the knock sensor wire harness connectors (3).

CAUTION: **When separating the catalytic converters from the manifolds, disconnect the oxygen sensor connectors. Allowing the catalytic converters to hang from the oxygen sensor wires damages the harness and/or sensors.**

NOTE: **Left side shown in illustration, right side similar.**

23. Disconnect all oxygen sensor wire harness connectors (2).
24. Saturate all exhaust bolts and nuts (3) with MoparÃ® Rust Penetrant. Allow five minutes for penetration.
25. Remove the both catalytic converter to manifold flange nuts (3) and separate the catalytic converters (4) from the exhaust manifolds.
26. Remove the starter. Refer to **STARTER, REMOVAL** .

54. Lower the vehicle.
55. Using a suitable jack, support the transmission.

NOTE: **Do not use air tools to install engine lift fixture.**

56. Install the engine lift fixture (special tool #8984B, Fixture, Engine Lifting) (2) and adapter (special tool #8984-UPD, Adapter, Engine Lift) (4).
57. Using a suitable engine hoist, separate the engine from the transmission and carefully remove the engine from the engine compartment.
58. Secure the engine onto a suitable engine stand.

INSTALLATION

INSTALLATION

CAUTION: **If the original engine has experienced a catastrophic failure or an individual failure with the piston, cylinder bore, engine block, valve or valve seat, the intake manifold MUST be replaced with a new manifold.**

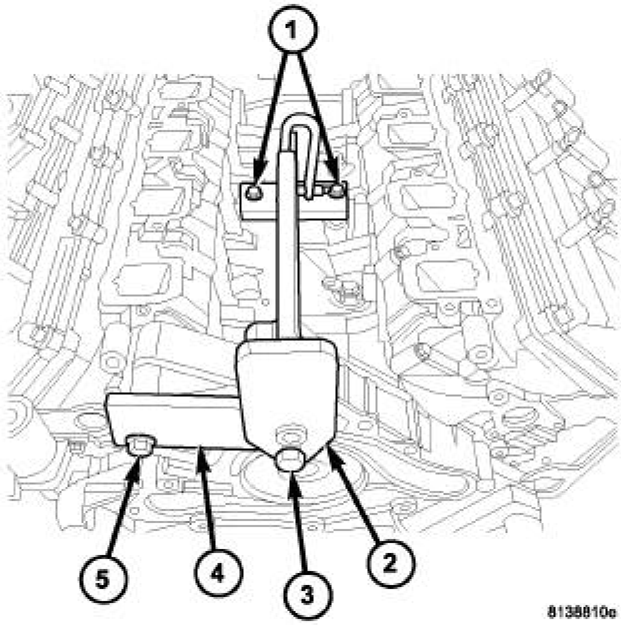

Fig. 34: Engine Lift Fixture And Adapter

NOTE: **Do not use air tools to install Engine Lift Fixture and Adapter (special tool #8984B, Fixture, Engine Lifting) (2, 3).**

1. Install the engine lift fixture (special tool #8984B, Fixture, Engine Lifting) (2) and adapter (special tool #8984-UPD, Adapter, Engine Lift) (4).
2. Using a suitable engine hoist, lower the engine into in the engine compartment.
3. Automatic transmission equipped vehicles, align the engine with the transmission.
4. Install two transmission to engine block mounting bolts finger tight.
5. Lower the engine assembly until the engine mounts rest in the engine cradle crossmember.

MDS SYSTEM

DESCRIPTION

DESCRIPTION

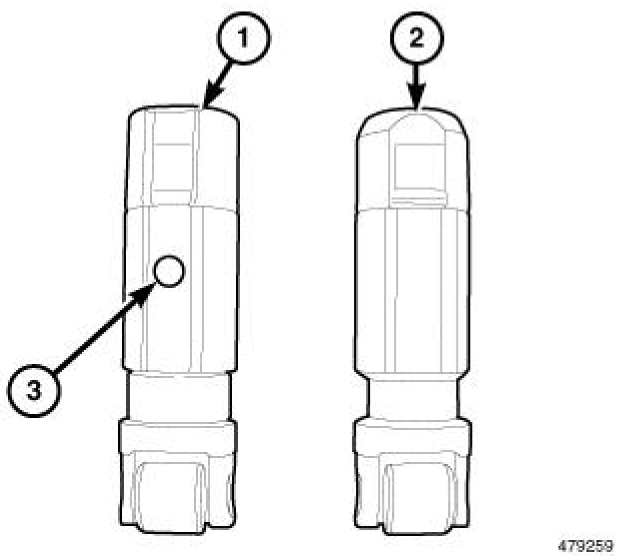

Fig. 61: MDS Lifter
Courtesy of CHRYSLER GROUP, LLC

The Multiple Displacement System (MDS) selectively deactivates cylinders 1, 4, 6 and 7 during steady speed, low acceleration and shallow grade climbing conditions to increase fuel economy.

The MDS can provide a 5 to 20% fuel economy benefit when operating in four-cylinder mode. Depending on driving habits and vehicle usage. For EPA rating purposes the fuel economy is 8 to 15% higher than if the engine was operating on eight-cylinders at all times.

The MDS deactivating lifter (1) can be distinguished from the non-MDS lifter (2) by the disconnecting pin (3) on the side of the MDS lifter.

MDS is integrated into the basic engine architecture requiring these additional components:

- Unique MDS camshaft
- 8 deactivating roller lifters
- 4 MDS control valve solenoids
- MDS control valve solenoid wiring harness
- Oil temperature sensor

OPERATION

OPERATION

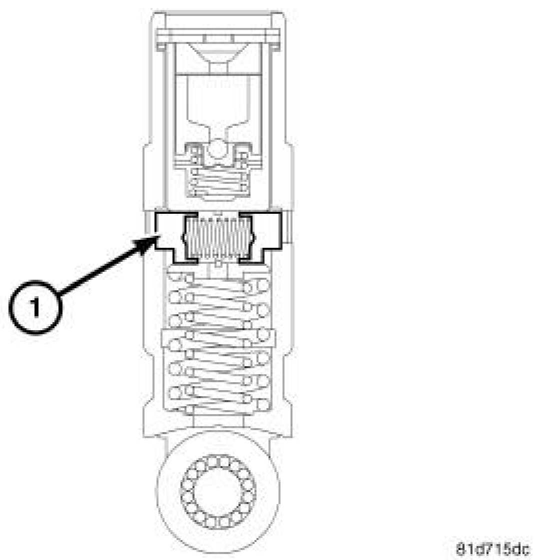

Fig. 62: MDS Lifter Cross-Section
Courtesy of CHRYSLER GROUP, LLC

The Multiple Displacement System (MDS) provides cylinder deactivation during steady speed, low acceleration and shallow grade climbing conditions to increase fuel economy. Both four and eight cylinder configurations have even firing intervals to provide smooth operation. The MDS selectively deactivates cylinders 1, 4, 6, and 7, to improve fuel economy. All deactivated cylinders have unique hydraulic lifters that collapse when deactivated to prevent the valves from opening. Engine oil pressure is used to activate and deactivate the valves. Oil is delivered through special oil passages drilled into the cylinder block. The MDS solenoid valves control the flow. When activated, pressurized oil pushes a latching pin on each MDS lifter which becomes a lost motion link. The base of the MDS lifter follows the camshaft while the top remains stationary. The MDS lifter is held in place against the pushrod by light spring pressure but unable to move because of the much higher force of the valve spring.

NOTE: **It is critical to use the recommended oil viscosity in engines that use MDS.**

Deactivation occurs during the compression stroke of each cylinder, after air and fuel enter the cylinder. Ignition occurs, but the combustion products remain trapped in the cylinder under high pressure, because the valves no longer open. No fuel/air enters or leaves during subsequent piston strokes, this high pressure gas is repeatedly

compressed and expanded like an air spring.

1. While sliding the air duct onto the throttle body, lower the air cleaner housing (5) into position and align the locating pin on the bottom of the housing.
2. Install the air cleaner body bolt (4) and securely tighten.
3. Install the makeup air hose (3) at the air cleaner body.
4. Connect the intake air temperature sensor wire harness connector (2).
5. Install the air duct retaining clamp (1) at the throttle body and securely tighten.

CYLINDER HEAD

OPERATION

OPERATION

The cylinder head closes the combustion chamber allowing the pistons to compress the air fuel mixture to the correct ratio for ignition. The valves located in the cylinder head open and close to either allow clean air into the combustion chamber or to allow the exhaust gases out, depending on the stroke of the engine.

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - CYLINDER HEAD GASKET FAILURE

A cylinder head gasket leak can be located between adjacent cylinders or between a cylinder and the adjacent water jacket.

- Possible indications of the cylinder head gasket leaking between adjacent cylinders are:
  - Loss of engine power
  - Engine misfiring
  - Poor fuel economy
- Possible indications of the cylinder head gasket leaking between a cylinder and an adjacent water jacket are:
  - Engine overheating
  - Loss of coolant
  - Excessive steam (white smoke) emitting from exhaust
  - Coolant foaming

CYLINDER-TO-CYLINDER LEAKAGE TEST

To determine if an engine cylinder head gasket is leaking between adjacent cylinders, follow the procedures in the Cylinder Compression Pressure Test. Refer to CYLINDER COMPRESSION TEST. An engine cylinder head gasket leaking between adjacent cylinders will results in approximately a 50 - 70% reduction in compression pressure.

CYLINDER-TO-WATER JACKET LEAKAGE TEST

WARNING: Use extreme care when the engine is operating with the coolant pressure cap removed. Failure to follow these instructions may result in possible serious or

fatal injury.

VISUAL TEST METHOD

With the engine cool, remove the coolant pressure cap. Start the engine and allow it to warm up until thermostat opens.

If a large combustion/compression pressure leak exists, bubbles will be visible in the coolant.

COOLING SYSTEM TESTER METHOD

CAUTION: With the cooling system tester in place, pressure builds up fast. Excessive pressure built up by continuous engine operation must be released to a safe pressure point. Never permit pressure to exceed 138 kPa (20 psi).

Install the commercially available Cooling System Tester to pressure cap neck. Start the engine and observe the tester's pressure gauge. If the gauge pulsates with every power stroke of a cylinder a combustion pressure leak is evident.

CHEMICAL TEST METHOD

Combustion leaks into the cooling system can also be checked by using the Bloc-Chek Kit (special tool #C-3685-A, Bloc-Chek Kit) or equivalent. Perform the test following the procedures supplied with the tool kit.

REMOVAL

REMOVAL

1. Perform the fuel system pressure release procedure. Refer to **FUEL DELIVERY, GAS, STANDARD PROCEDURE** .
2. Disconnect and isolate the negative battery cable.

4. Raise and support the vehicle. Refer to **HOISTING, STANDARD PROCEDURE** .
5. Remove retainers (1) and the belly pan.
6. Drain the cooling system. Refer to **STANDARD PROCEDURE** .

CAUTION: **When separating the catalytic converters from the manifolds, disconnect the oxygen sensor connectors. Allowing the catalytic converters to hang from the oxygen sensor wires damages the harness and/or sensors.**

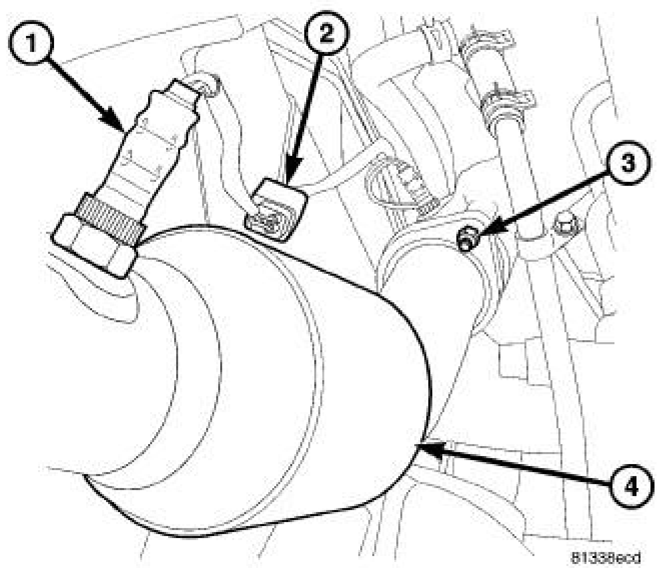

Fig. 71: LH Catalytic Converter
Courtesy of CHRYSLER GROUP, LLC

NOTE: **Left side shown in illustration, right side similar.**

7. Disconnect all oxygen sensor wire harness connectors (2).
8. Saturate all exhaust bolts and nuts (3) with MoparÃ® Rust Penetrant. Allow five minutes for penetration.
9. Remove nuts (3) and separate the catalytic converters (4) from the exhaust manifolds.
10. Remove support and lower the vehicle.
11. Remove the serpentine belt. Refer to **BELT, SERPENTINE, REMOVAL** .
12. Remove the cylinder head cover. Refer to **COVER(S), CYLINDER HEAD, REMOVAL, 5.7L**.
13. If removing the right cylinder head, remove nut and the oil dip stick tube.

CAUTION: Pushrods and rocker arm assemblies must be installed in their original locations or engine damage could result.

NOTE: Make sure to identify the original location of the rocker arms and push rods for correct assembly.

14. Remove the rocker arms and push rods. Refer to **ROCKER ARM, VALVE, REMOVAL, 5.7L**.

NOTE: It is not necessary to remove the exhaust manifolds to remove the cylinder heads.

15. Using the sequence shown in illustration, remove the cylinder head bolts and remove the cylinder head(s).
16. Remove and discard the cylinder head gasket.
17. Inspect and clean the cylinder head (2) mating surface.

18. If necessary, remove bolts and the manifold (2).

CLEANING

CLEANING

Clean all sealing surfaces of the cylinder block and cylinder heads using MoparÂ® Brake Parts Cleaner (or equivalent).

INSPECTION

INSPECTION

1. Inspect the cylinder head for out-of-flatness using a straightedge and a feeler gauge. If tolerances exceed 0.0508 mm (0.002 in.) replace the cylinder head.
2. Inspect the valve seats for damage. Service the valve seats as necessary.
3. Inspect the valve guides for wear, cracks or looseness. If either condition exist, replace the cylinder head.
4. Inspect the pushrods. Replace worn or bent pushrods.
5. Inspect the cylinder head bolts.

INSTALLATION

INSTALLATION

CAUTION: Make sure that the retainers (1) and the rocker arms (2) are not overlapped when tightening bolts or engine damage could result.

CAUTION: Due to the changes in the pushrod clearance holes in the Eagle 5.7L cylinder heads, close attention must be given when installing the pushrod(s) into the tappet(s). Once the pushrod(s) have been installed, use a suitable light to look down through the pushrod hole(s). This will allow you to verify the pushrod(s) are centered properly in the tappet(s) and avoid engine damage. Recheck after the rocker shaft assembly has been installed and tightened to specification.

CAUTION: **Due to the changes in the pushrod clearance holes in the Eagle 5.7L cylinder heads, close attention must be given when installing the pushrod(s) into the tappet(s). Once the pushrod(s) have been installed, use a suitable light to look down through the pushrod hole(s). This will allow you to verify the pushrod(s) are centered properly in the tappet(s)**

and avoid engine damage. Recheck after the rocker shaft assembly has been installed and tightened to specification.

CAUTION: **The longer pushrods are for the exhaust side and the shorter pushrods are for the intake side.**

NOTE: **Pushrods must be installed in the same order as removed.**

7. Install the pushrods and rocker arm shaft. Refer to **ROCKER ARM, VALVE, INSTALLATION, 5.7L**.
8. Using the sequence shown in illustration, tighten the rocker shaft bolts to 22 N.m (16 ft. lbs.).

CAUTION: **Do not use harsh cleaners to clean the cylinder head covers. Severe damage to covers may occur.**

CAUTION: **Do not allow other components including the wire harness to rest on or against the engine cylinder head cover. Prolonged contact with other objects may wear a hole in the cylinder head cover.**

10. Clean the cylinder head cover and both sealing surfaces, inspect and replace the gasket as necessary.
11. Install the cylinder head cover and hand start all fasteners. Verify that all double ended studs are in the correct location.
12. Using the sequence shown in illustration, tighten the cylinder head cover retaining bolts to 8 N.m (71 in. lbs.).
13. Install the spark plugs.

15. Install the ignition coil (2) on the plugs and tighten the fasteners (3) to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
16. Connect the ignition coil wire harness connectors (1).
17. Install the air intake resonator and the air cleaner assembly Refer to **BODY, AIR CLEANER, INSTALLATION, 5.7L**.
18. Connect the negative battery cable.

VALVES, INTAKE AND EXHAUST

DESCRIPTION

VALVE GUIDES

The valve guides are made of powdered metal and pressed into the cylinder head. The guides are not replaceable or serviceable, and valve guide reaming is not recommended. If the guides are worn beyond acceptable limits, replace the cylinder heads.

VALVES

Both the intake and the exhaust valves are made of steel. The intake valve is 50.93 mm (2.00 inches) in diameter and the exhaust valve is 39.53 mm (1.55 inches) in diameter. All valves use three-bead lock keepers to retain the springs and promote valve rotation.

STANDARD PROCEDURE

STANDARD PROCEDURE - REFACING

VALVE FACE AND VALVE SEAT ANGLE CHART

DESCRIPTION	SPECIFICATION	
-	Metric	Standard
Seat Width		
Intake	1.18 - 1.62 mm	0.0464 - 0.0637 in.
Exhaust	1.48 - 1.92 mm	0.058 - 0.075 in.
Face Angle	45Ā° - 45 1/2 Ā°	
Seat Angle	44 1/2 Ā° - 45Ā°	

NOTE: **Valve seats that are worn or burned can be reworked, provided that correct angle and seat width are maintained. Otherwise the cylinder head must be replaced.**

NOTE: **When refacing valves and valve seats, it is important that the correct size valve guide pilot be used for reseating stones. A true and complete surface must be obtained.**

1. Using a suitable dial indicator, measure the center of the valve seat. Total run out must not exceed 0.051 mm (0.002 in).
2. Apply a small amount of Prussian Blue to the valve seat. Insert the valve into the cylinder head. Rotate valve while applying light pressure on the valve seat. Remove the valve and examine the valve face. If the blue is transferred below the top edge of the valve face, lower the valve seat using a 15 degree stone. If the blue is transferred to the bottom edge of the valve face, raise the valve seat using a 65 degree stone.
3. When the seat is properly positioned the width of the intake seat must be 1.18 - 1.62 mm (0.0464 - 0.0637 in.) and the exhaust seat must be 1.48 - 1.92 mm (0.058 - 0.075 in.).
4. Check the valve spring installed height after refacing the valve and seat. The installed height for both intake and exhaust valve springs must not exceed 46.0 mm (1.81 in.).
5. The valve seat must maintain a seat angle of 44 1/2 Ā° - 45Ā°.
6. The valve face must maintain a face angle of 45Ā° - 45 1/2 Ā°.

REMOVAL

REMOVAL

1. Remove the cylinder head. Refer to **CYLINDER HEAD, REMOVAL, 5.7L**.
2. Compress valve springs using Valve Spring Compressor Tool (special tool #C-3422-D, Compressor, Valve Spring) and Adapter (special tool #8464, Adapter, Valve Spring).
3. Remove valve retaining locks, valve spring retainers, valve stem seals and valve springs.
4. Before removing valves, remove any burrs from valve stem lock grooves to prevent damage to the valve guides. Identify valves to ensure installation in original location.

INSTALLATION

INSTALLATION

1. Clean valves thoroughly. Discard burned, warped and cracked valves.
2. Remove the carbon and varnish deposits from the inside of the valve guides with a reliable guide cleaner.
3. Measure the valve stems for wear. If the wear exceeds 0.051 mm (0.002 inch), replace the valve.
4. Coat the valve stems with clean engine oil and insert them into the cylinder head.
5. If the valves or seats are ground, check the valve stem height. If the valve stem is too long, replace the cylinder head.
6. Install new seals on all valve guides. Install the valve springs and valve retainers.
7. Compress the valve springs with the Valve Spring Compressor (special tool #C-3422-D, Compressor, Valve Spring) and Valve Spring Adapter (special tool #8464, Adapter, Valve Spring). Install the locks and release the tool. If the valves and/or seats are ground, measure the installed height of the springs. Make sure the measurement is taken from the bottom of the spring seat in the cylinder head to the bottom surface of the spring retainer.
8. Install the cylinder head. Refer to **CYLINDER HEAD, INSTALLATION, 5.7L**.

ENGINE BLOCK

CLEANING

CLEANING

Thoroughly clean the oil pan and engine block gasket surfaces.

Use compressed air to clean:

- Gallery at the oil filter adaptor hole
- Front and rear oil gallery holes
- Multiple Displacement System (MDS) oil gallery holes in the valley
- Oil feed holes for the crankshaft main bearings

Drilled and tapped holes should be free of debris upon assembly.

Once the block has been completely cleaned, apply LoctiteÂ® PST pipe sealant with Teflon 592 to the threads of the front and rear oil gallery plugs and coolant drain plugs. Tighten the oil gallery 1/4 inch x 18 NPT plugs to the proper specification. Refer to **TORQUE SPECIFICATIONS**. Tighten the coolant drain 1/4 inch x 18 NPT

plugs to the proper specification. Refer to **TORQUE SPECIFICATIONS**. Tighten the 3/8 inch x 18 NPT plugs to the proper specification. Refer to **TORQUE SPECIFICATIONS**.

INSPECTION

INSPECTION

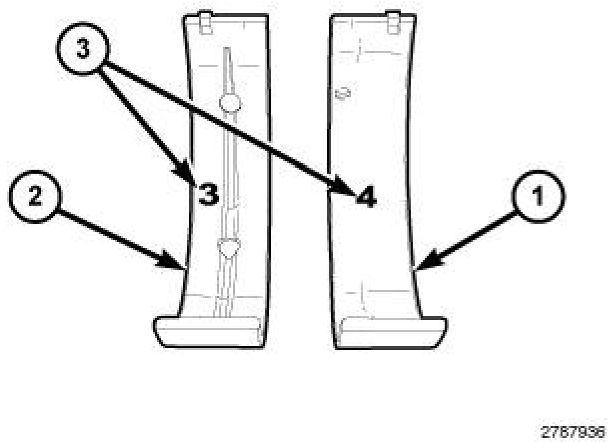

Fig. 115: Main Bearing Inserts
Courtesy of CHRYSLER GROUP, LLC

1. Wipe the main bearing inserts (1, 2) clean.
2. Inspect the inserts for abnormal wear patterns, scoring, grooving, fatigue, pitting and for metal or other foreign material imbedded in the lining.
3. Inspect the back of the inserts for fractures, scrapes or irregular wear patterns.
4. Inspect the insert locking tabs for damage.
5. Inspect the crankshaft thrust washers for scoring, scratches, wear or blueing.
6. Replace any bearing that shows abnormal wear.
7. Inspect the main bearing bores for signs of scoring, nicks and burrs.
8. If the cylinder block main bearing bores show damage, replace the engine block.

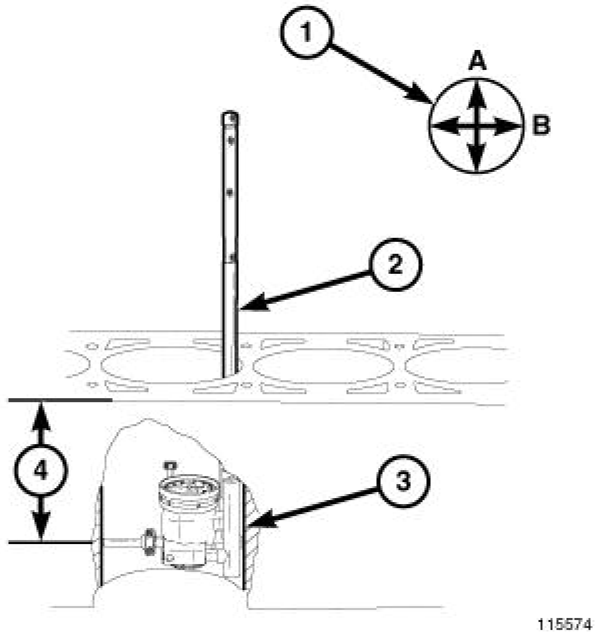

Fig. 116: Measuring Cylinder Bore Diameter
Courtesy of CHRYSLER GROUP, LLC

9. Use Cylinder Indicator (special tool #C-119, Cylinder Indicator) (2) to correctly measure the inside diameter of the cylinder bore (3). A cylinder bore gauge capable of reading in 0.003 mm (0.0001 in.) Increments is required. If a bore gauge is not available, do not use an inside micrometer.
10. Measure the inside diameter of the cylinder bore at three levels below the top of the bore (4). Start at the top of the bore, perpendicular (across or at 90Ā°) to the axis of the crankshaft at point A (1).
11. Repeat the measurement near the middle of the bore then repeat the measurement near the bottom of the bore.
12. Determine the taper by subtracting the smaller diameter from the larger diameter.
13. Rotate the measuring device 90Ā° to point B (1) and repeat the three measurements. Verify that the maximum taper is within specification. Refer to **ENGINE SPECIFICATIONS**.
14. Determine out-of-roundness by comparing the difference between each measurement.
15. If the cylinder bore taper and out-of-roundness does not exceed. Refer to **ENGINE SPECIFICATIONS**. Then the cylinder bore can be honed. If the cylinder bore taper or out- of-round condition exceeds the maximum limits, replace the cylinder block.

NOTE: **A slight amount of taper always exists in the cylinder bore after the engine has been in use for a period of time.**

ASSEMBLY, VARIABLE VALVE TIMING

DESCRIPTION

DESCRIPTION

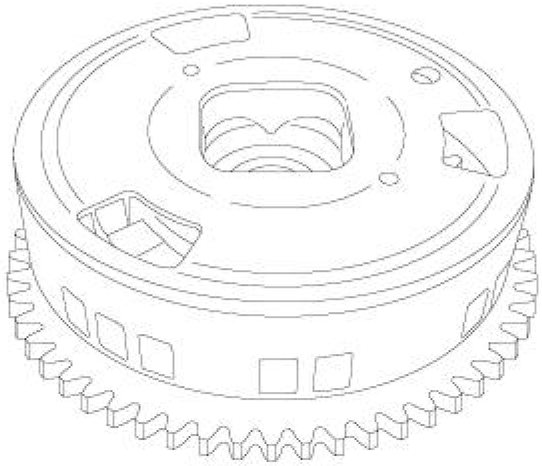

Fig. 117: Variable Cam Timing (VCT) Assembly
Courtesy of CHRYSLER GROUP, LLC

The 5.7L engine is equipped with Variable Cam Timing (VCT). This system advances and/or retards the camshaft timing to improve engine performance, mid-range torque, idle quality, fuel economy, and reduce emissions. The VCT assembly is sometimes referred to as a camshaft phaser.

CAUTION: Never attempt to disassemble the camshaft phaser, severe engine damage could result.

The VCT assembly consists of the camshaft sprocket and a timing phaser. The VCT phaser assembly bolts to the camshaft and is serviced as an assembly.

OPERATION

OPERATION

The Variable Cam Timing (VCT) assembly is actuated with engine oil pressure. The oil flow to the VCT assemblies are controlled by an Oil Control Valve (OCV). The OCV consist of a Pulse Width Modulated (PWM) solenoid and a spool valve. The Powertrain Control Module (PCM) actuates the OCV to control oil flow through the spool valve into the VCT assemblies. The VCT assembly consists of a rotor, stator, and sprocket. The stator is connected to the timing chain through the sprocket. The rotor is connected to the camshaft. Oil flow in to the VCT assembly rotates the rotor with respect to the stator, thus rotating the exhaust camshaft with respect to the timing chain and intake camshaft. An infinitely variable cam timing position can be achieved within the limits of the hardware. The CMP monitors the position of the camshaft with respect to the crankshaft and provides feedback to the PCM.

CAUTION: Never attempt to disassemble the camshaft phaser, severe engine damage could result.

REMOVAL

REMOVAL

CAUTION: Never attempt to disassemble the camshaft phaser, severe engine damage could result.

1. Remove the engine timing cover. Refer to **COVER(S), ENGINE TIMING, REMOVAL, 5.7L**.
2. Remove bolt (1) and the camshaft phaser (2).

INSTALLATION

INSTALLATION

CAUTION: Never attempt to disassemble the camshaft phaser, severe engine damage could result.

2. Position the phaser (2) in place and install phaser retaining bolt (1) and tighten to the proper specification. Refer to TORQUE SPECIFICATIONS.
3. Install the engine timing cover. Refer to COVER(S), ENGINE TIMING, INSTALLATION, 5.7L.

BEARING(S), CRANKSHAFT, MAIN

STANDARD PROCEDURE

STANDARD PROCEDURE - CRANKSHAFT MAIN BEARING - FITTING

MAIN BEARING JOURNAL DIAMETER (CRANKSHAFT REMOVED)

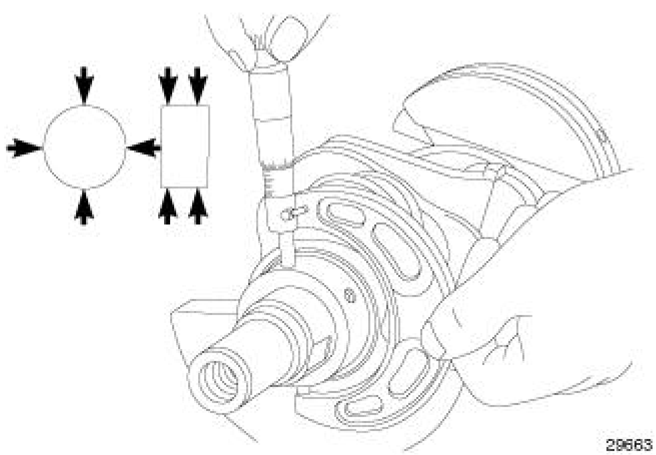

Fig. 121: Crankshaft Journal Measurements - Typical
Courtesy of CHRYSLER GROUP, LLC

With the crankshaft removed from the cylinder block.

Clean the oil off the main bearing journal.

Determine the maximum diameter of the journal with a micrometer. Measure at two locations 90Ā° apart at each end of the journal.

The maximum allowable taper is 0.008 mm (0.0004 inch.) and maximum out of round is 0.005 mm (0.0002 inch). Compare the measured diameter with the journal diameter specification (Main Bearing Fitting Chart). Select the inserts required to obtain the specified bearing-to-journal clearance.

CRANKSHAFT MAIN BEARING SELECTION

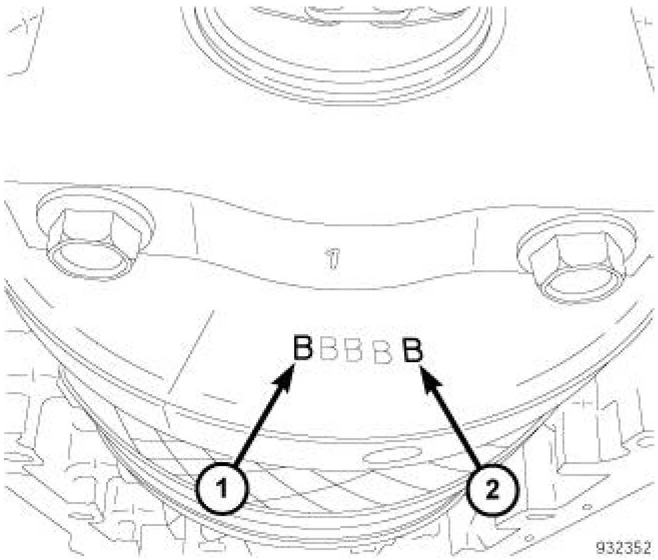

Fig. 122: Crankshaft Counterweight Stamped Grade Identification Marks
Courtesy of CHRYSLER GROUP, LLC

The main bearings are "select fit" to achieve proper oil clearances. For main bearing selection, the crankshaft counterweight has grade identification marks stamped into it. These marks are read from left to right. The left letter (1) refers to the number one main journal and the right letter (2) refers to the number 5 journal.

NOTE: **Service main bearings are coded. These codes identify what size or grade of the bearing.**

MAIN BEARING SELECTION CHART - 5.7L

GRADE MARKING	BEARING SIZE		FOR USE WITH JOURNAL SIZE	
-	METRIC	STANDARD	METRIC	STANDARD
A	0.008 mm U/S	0.0004 in. U/S	64.988 - 64.995 mm	2.5585 - 2.5588 in.
B	NOMINAL		64.996 - 65.004 mm	2.5588 - 2.5592 in.
C	0.008 mm O/S	0.0004 in. O/S	65.005 - 65.012 mm	2.5592 - 2.5595 in.

INSPECTION

INSPECTION

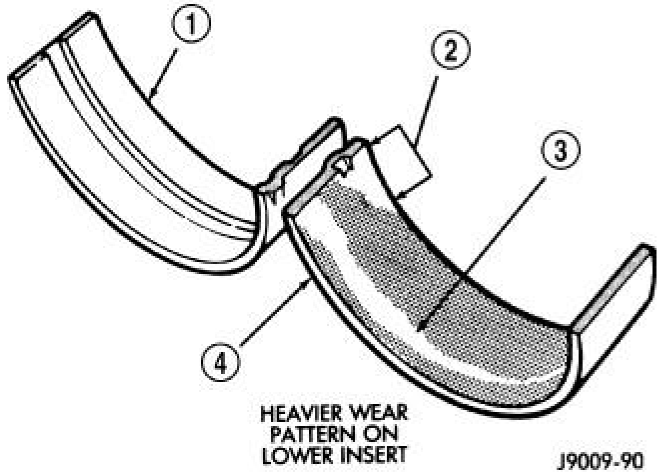

Fig. 123: Main Bearing Wear Patterns
Courtesy of CHRYSLER GROUP, LLC

Wipe the inserts clean and inspect for abnormal wear patterns and for metal or other foreign material imbedded in the lining. Normal main bearing insert wear patterns are illustrated.

NOTE: **If any crankshaft journals are scored, the crankshaft must be repaired or replaced.**

Inspect the back of the inserts for fractures, scrapings or irregular wear patterns.

Inspect the upper insert locking tabs for damage.

Replace all damaged or worn bearing inserts.

CAMSHAFT, ENGINE

REMOVAL

CAMSHAFT CORE HOLE PLUG

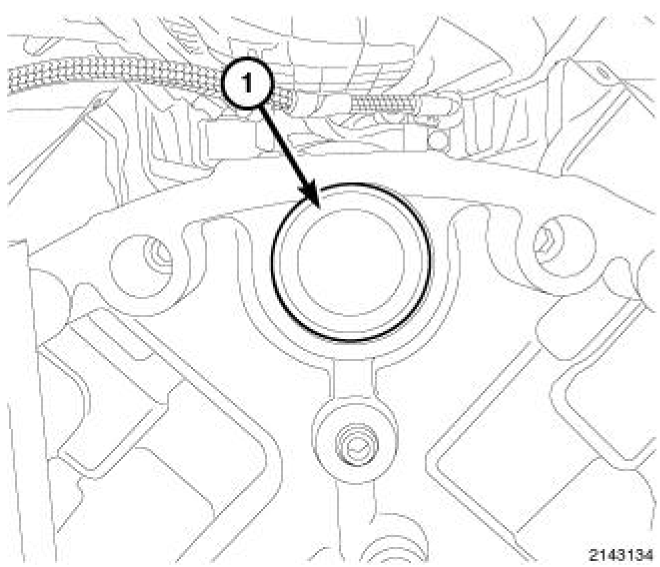

Fig. 124: Camshaft Core Hole Plug

Courtesy of CHRYSLER GROUP, LLC

1. Perform the fuel system pressure release procedure. Refer to **FUEL DELIVERY, GAS, STANDARD PROCEDURE** .
2. Remove the engine from the vehicle. Refer to **REMOVAL, 5.7L**.
3. On automatic transmission models, remove the flexplate. Refer to **FLEXPLATE, REMOVAL, 5.7L**.
4. On manual transmission models, remove the flywheel. Refer to **FLYWHEEL, REMOVAL** .

CAUTION: Do not damage the rear surface of the camshaft or the core plug sealing surface, when removing the core plug.

5. Using a suitable sharp punch, punch a small hole in the camshaft core hole plug (1).
6. Insert a short sheet metal screw into the small hole in the camshaft core hole plug.
7. Using a suitable slide hammer puller, remove the rear camshaft core hole plug.

CAMSHAFT

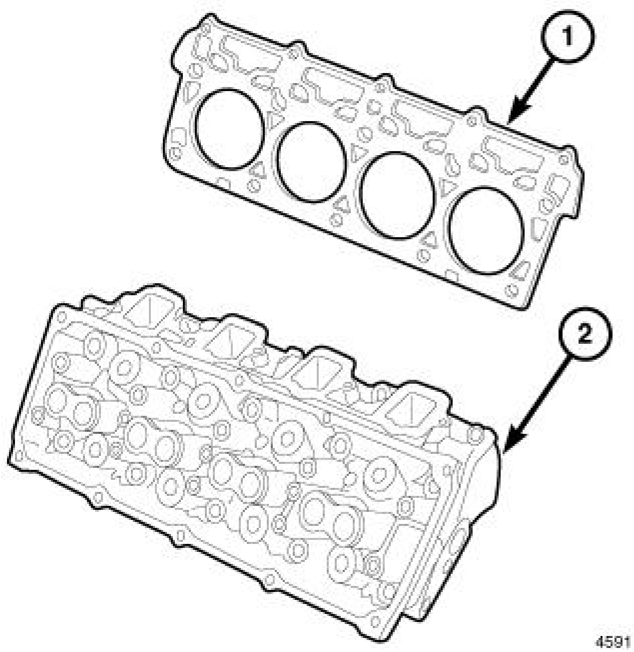

Fig. 125: Cylinder Head & Gasket
Courtesy of CHRYSLER GROUP, LLC

1. Remove both cylinder heads (2). Refer to **CYLINDER HEAD, REMOVAL, 5.7L**.

CAUTION: The 5.7L Multi Displacement System (MDS) engine uses both standard roller lifters and deactivating roller lifters. The deactivating roller lifters must be used in cylinders 1, 4, 6, 7. The deactivating lifters can be identified by the two holes in the side of the lifter body, for the latching pins.

CAUTION: Whenever the camshaft is replaced, all lifters must be replaced. If the lifter and retainer assemblies are to be reused, identify the lifters to ensure

installation in their original location or engine damage could result.

CAUTION: The lifter and retainer assembly must be installed as a unit.

2. Remove the lifters and retainer as an assembly. Refer to **LIFTER(S), HYDRAULIC, ROLLER, REMOVAL, 5.7L**.
3. Remove the generator. Refer to **GENERATOR, REMOVAL** .
4. Remove the A/C compressor. Refer to **COMPRESSOR, A/C, REMOVAL** .
5. Remove the radiator. Refer to **RADIATOR, ENGINE COOLING, REMOVAL** .
6. Remove the A/C condenser. Refer to **CONDENSER, A/C, REMOVAL** .
7. Raise and support vehicle. Refer to **HOISTING, STANDARD PROCEDURE** .
8. Remove the oil pump pickup tube (1). Refer to **PAN, OIL, REMOVAL, 5.7L**.
9. Remove support and lower the vehicle.
10. Remove the timing chain and camshaft phaser. Refer to **CHAIN AND SPROCKETS, TIMING, REMOVAL, 5.7L**.

12. Install a long bolt (2) into the front of the camshaft to aid in removal.
13. Remove the camshaft using care not to damage the camshaft bearings with the camshaft lobes (1).

INSPECTION

INSPECTION

The cam bearings are not serviceable. Do not attempt to replace cam bearings for any reason. If the cam bearings are damaged, the cylinder block must be replaced.

INSTALLATION

CAMSHAFT CORE HOLE PLUG

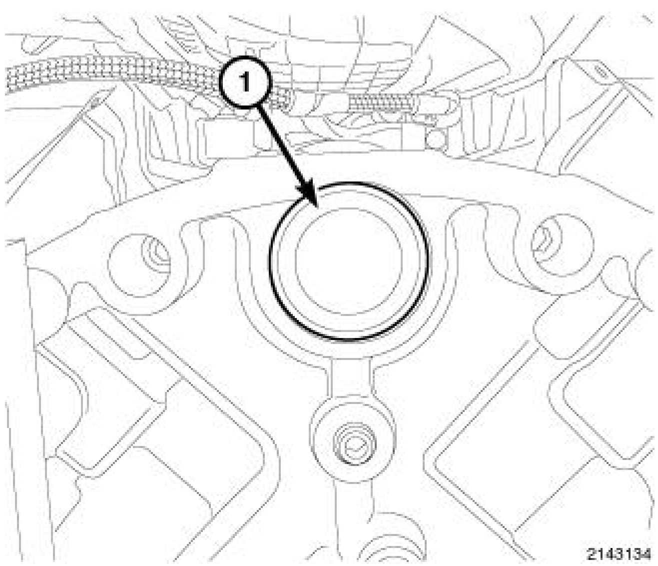

Fig. 128: Camshaft Core Hole Plug

Courtesy of CHRYSLER GROUP, LLC

1. Clean the core hole in the cylinder block.

NOTE: **Do not apply adhesive to the new camshaft core hole plug. A new plug has adhesive pre-applied.**

2. Install a new camshaft core hole plug (1) located at the rear of cylinder block, using a suitable flat faced tool. The plug must be fully seated on the cylinder block shoulder.
3. On manual transmission models, install the flywheel. Refer to **FLYWHEEL, INSTALLATION** .
4. On automatic transmission models, install the flexplate. Refer to **FLEXPLATE, INSTALLATION, 5.7L**.
5. Install the engine. Refer to **INSTALLATION, 5.7L**.

CAMSHAFT

CAUTION: **The 5.7L engine uses a unique camshaft for use with the Multi Displacement System (MDS). When installing a new camshaft, the replacement camshaft must be compatible with MDS.**

CAUTION: **Use care when installing the camshaft into the engine block, do not damage the camshaft bearings with the camshaft lobes.**

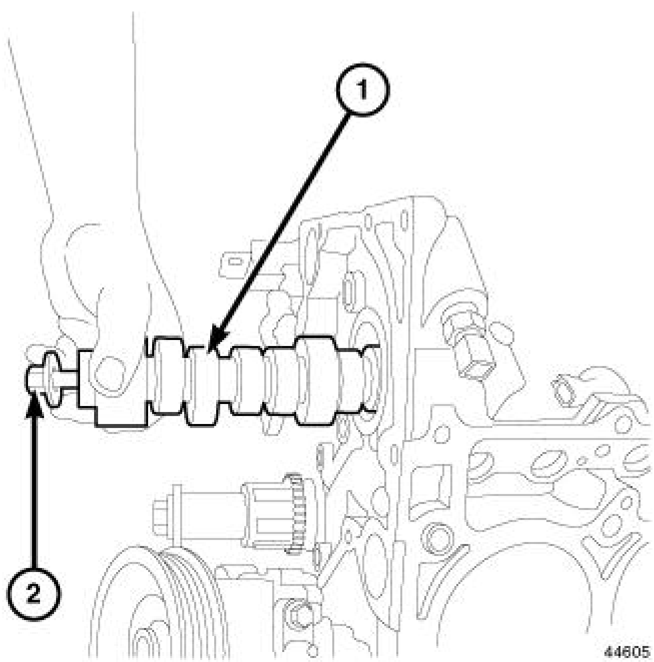

Fig. 129: Removing/Installing Camshaft

3. Install the camshaft thrust plate (1) and tighten retaining bolts to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
4. Install the timing chain (5) and camshaft phaser (1). Refer to **CHAIN AND SPROCKETS, TIMING, INSTALLATION, 5.7L**.
5. Using a suitable dial indicator, measure the camshaft end play. Refer to **ENGINE SPECIFICATIONS**. If not within specification, install a new thrust plate.
6. Install the oil pump. Refer to **PUMP, ENGINE OIL, INSTALLATION, 5.7L**.
7. Raise and support vehicle.
8. Install the oil pump pickup tube and oil pan. Refer to **PAN, OIL, INSTALLATION, 5.7L**.
9. Remove support and lower the vehicle.
10. Install the A/C condenser. Refer to **CONDENSER, A/C, INSTALLATION** .
11. Install the radiator. Refer to **RADIATOR, ENGINE COOLING, INSTALLATION** .
12. Install the A/C compressor. Refer to **COMPRESSOR, A/C, INSTALLATION** .
13. Install the generator. Refer to **GENERATOR, INSTALLATION** .

CAUTION: The 5.7L Multi Displacement System (MDS) engine uses both standard roller lifters and deactivating roller lifters. The deactivating roller lifters must be used in cylinders 1, 4, 6, 7. The deactivating lifters can be identified by the two holes in the side of the lifter body, for the latching pins.

CAUTION: Whenever the camshaft is replaced, all lifters must be replaced. If the lifter and retainer assemblies are to be reused, identify the lifters to ensure installation in their original location or engine damage could result.

CAUTION: The lifter and retainer assembly must be installed as a unit.

14. Install the lifters (2) and retainer (1) as an assembly into their original location. Refer to **LIFTER(S),**

HYDRAULIC, ROLLER, INSTALLATION, 5.7L.

DAMPER, VIBRATION

DESCRIPTION

DESCRIPTION

The crankshaft damper is used to control the resonance that is produced by the engine. The Noise, Vibration, and Harshness (NVH) created from the crankshaft can be controlled by dissipating the torque energy through the damper.

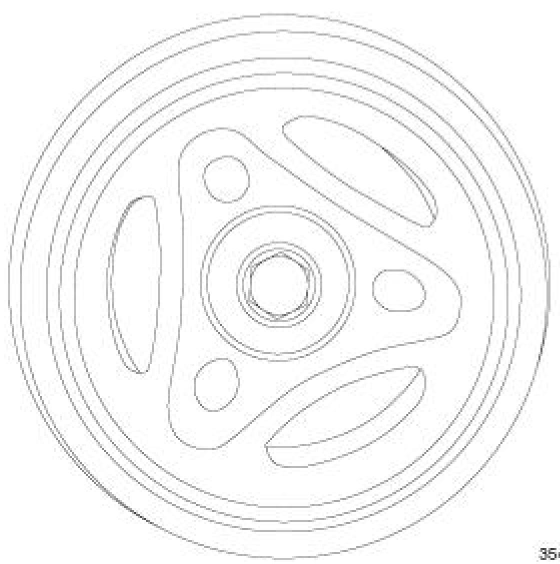

Fig. 148: Crankshaft Damper & Harden Steel Bolt
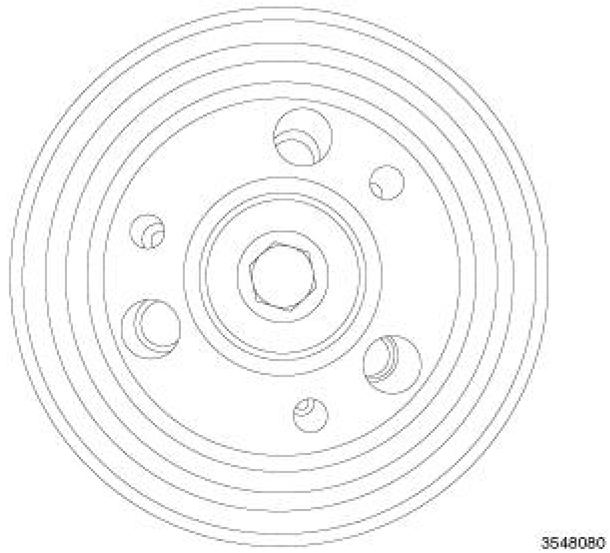
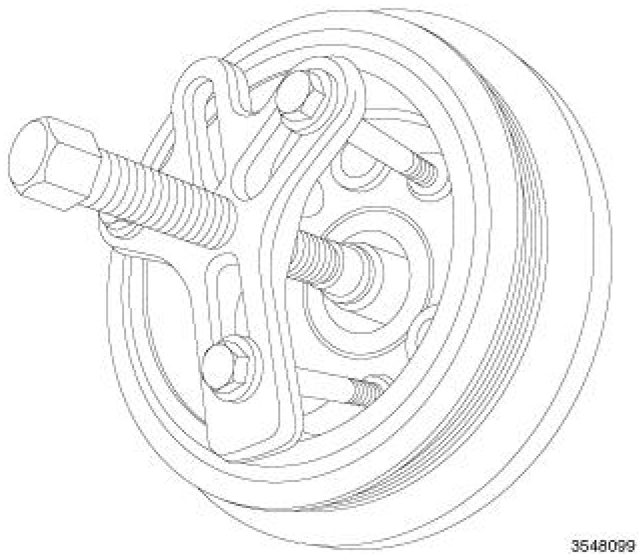
Courtesy of CHRYSLER GROUP, LLC

The crankshaft damper is held to the crankshaft by means of a harden steel bolt. The damper is pressed onto a specific machined surface of the crankshaft.



[Fig. 149: HEMIĀ® Engine Crankshaft Damper]
Courtesy of CHRYSLER GROUP, LLC

The HEMIĀ® Engines incorporate various crankshaft vibration dampers depending on the engine application.



[Fig. 150: Removing Vibration Damper]
Courtesy of CHRYSLER GROUP, LLC

Finding the proper puller for the application will ensure no damage will come to the damper. The flange puller is used by installing 3 bolts into the pre-tapped holes in the damper.

LIFTER(S), HYDRAULIC, ROLLER

DESCRIPTION

DESCRIPTION

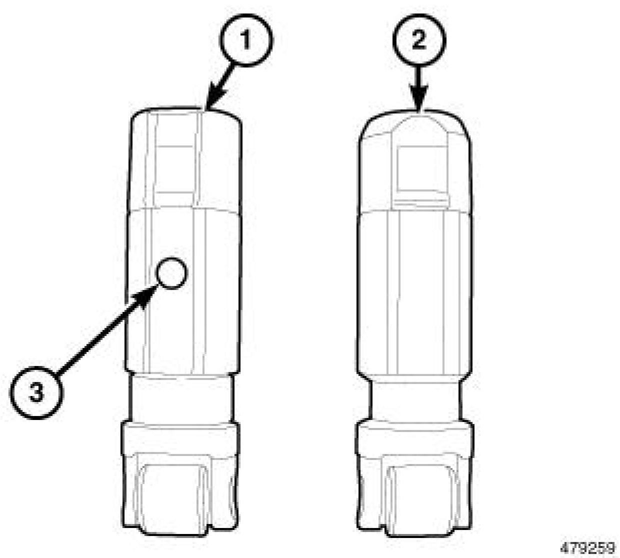

Fig. 157: MDS Lifter
Courtesy of CHRYSLER GROUP, LLC

The Multiple Displacement System (MDS) selectively deactivates cylinders 1, 4, 6 and 7 during steady speed, low acceleration and shallow grade climbing conditions to increase fuel economy.

The MDS can provide a 5 to 20% fuel economy benefit when operating in four-cylinder mode. Depending on

driving habits and vehicle usage. For EPA rating purposes the fuel economy is 8 to 15% higher than if the engine was operating on eight-cylinders at all times.

The MDS deactivating lifter (1) can be distinguished from the non-MDS lifter (2) by the disconnecting pin (3) on the side of the MDS lifter.

MDS is integrated into the basic engine architecture requiring these additional components:

- Unique MDS camshaft
- 8 deactivating roller lifters
- 4 MDS control valve solenoids
- MDS control valve solenoid wiring harness
- Oil temperature sensor

OPERATION

OPERATION

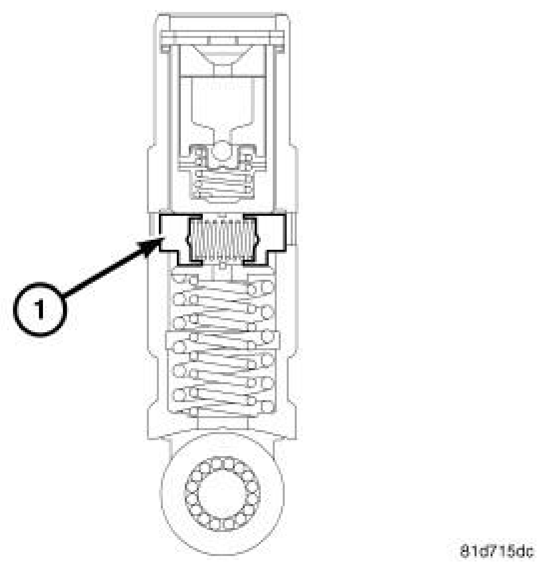

Fig. 158: MDS Lifter Cross-Section
Courtesy of CHRYSLER GROUP, LLC

The Multiple Displacement System (MDS) provides cylinder deactivation during steady speed, low acceleration and shallow grade climbing conditions to increase fuel economy. Both four and eight cylinder configurations have even firing intervals to provide smooth operation. The MDS selectively deactivates cylinders 1, 4, 6, and 7, to improve fuel economy. All deactivated cylinders have unique hydraulic lifters that collapse when deactivated to prevent the valves from opening. Engine oil pressure is used to activate and deactivate the valves. Oil is delivered through special oil passages drilled into the cylinder block. The MDS solenoid valves control the flow. When activated, pressurized oil pushes a latching pin on each MDS lifter which becomes a lost motion link. The base of the MDS lifter follows the camshaft while the top remains stationary. The MDS lifter is held in place against the pushrod by light spring pressure but unable to move because of the much higher force of the valve spring.

NOTE: **It is critical to use the recommended oil viscosity in engines that use MDS.**

Deactivation occurs during the compression stroke of each cylinder, after air and fuel enter the cylinder. Ignition occurs, but the combustion products remain trapped in the cylinder under high pressure, because the valves no longer open. No fuel/air enters or leaves during subsequent piston strokes, this high pressure gas is repeatedly compressed and expanded like an air spring.

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - HYDRAULIC TAPPETS

Check the oil pressure before disassembling any part of the engine to correct tappet noise. If vehicle has no oil pressure gauge, install a reliable gauge at the pressure sending-unit. The pressure should be between 107-758 kPa (25-110 psi) at 3, 000 RPM. Refer to **DIAGNOSIS AND TESTING**.

Check the oil level after the engine reaches normal operating temperature. Allow five minutes for the oil level to stabilize before checking the oil level. The oil level in the pan should never be above the FULL mark or below the ADD OIL mark on the dipstick. Either of these two conditions could be responsible for noisy tappets.

OIL LEVEL

HIGH

If the oil level is above the FULL mark, it is possible for the connecting rods to dip into the oil. With the engine running, this condition could create foam in the oil pan. Foam in the oil pan would be fed to the hydraulic tappets by the oil pump causing them to lose length and allow the valves to seat noisily.

LOW

Low oil level may allow the oil pump to take in air. When air is fed to the tappets, they lose length, which allows valves to seat noisily. Any leaks on the intake side of the oil pump through which air can be drawn creates the same tappet action. Check the lubrication system from the intake strainer to the pump cover, including the relief valve retainer cap. When tappet noise is due to aeration, it may be intermittent or constant, and usually more than one tappet will be noisy. When the oil level and leaks have been corrected, operate the engine at fast idle. Run the engine for a sufficient amount of time to allow all of the air inside the tappets to be bleed out.

TAPPET NOISE DIAGNOSIS

1. To determine the source of tappet noise, crank the engine over with the cylinder head covers removed.
2. Feel each valve spring or rocker arm to detect the noisy tappet. The noisy tappet will cause the affected spring and/or rocker arm to vibrate or feel rough in operation.

   NOTE: **Worn valve guides or cocked springs are sometimes mistaken for noisy tappets. If such is the case, noise may be dampened by applying side thrust on the valve spring. If noise is not appreciably reduced, it can be assumed the noise is in the tappet. Inspect the rocker arm pushrod sockets and pushrod ends for wear.**

3. Valve tappet noise ranges from light noise to a heavy click. A light noise is usually caused by excessive leak-down around the unit plunger, or by the plunger partially sticking in the tappet body cylinder. The tappet should be replaced. A heavy click is caused by a tappet check valve not seating, or by foreign particles wedged between the plunger and the tappet body. This will cause the plunger to stick in the

down position. This heavy click will be accompanied by excessive clearance between the valve stem and rocker arm as valve closes. In either case, tappet assembly should be removed for inspection and cleaning.

4. The valve train generates a noise very much like a light tappet noise during normal operation. Care must be taken to ensure that tappets are making the noise. If more than one tappet seems to be noisy, it's probably not the tappets.

REMOVAL

REMOVAL

1. Disconnect and isolate the negative battery cable.
2. Remove the cylinder head. Refer to CYLINDER HEAD, REMOVAL, 5.7L.

CAUTION: The lifter and retainer assembly must be installed as a unit.

CAUTION: If the lifter and retainer assembly are to be reused, identify the lifters to ensure installation in their original location or engine damage could result.

4. Remove the tappet guide holder (1) and tappets (2) as an assembly.
5. Check the camshaft lobes for abnormal wear.

INSTALLATION

INSTALLATION

The Multiple Displacement System (MDS) provides cylinder deactivation during steady speed, low acceleration and shallow grade climbing conditions to increase fuel economy.

CAUTION: Engines equipped with MDS use both standard roller lifters (2) and deactivating roller lifters (1). The deactivating roller lifters must be used in cylinders 1, 4, 6, 7. The deactivating lifters can be identified by the two holes in the side of the lifter body (3), for the latching pins.

CAUTION: The lifter and retainer assembly must be installed as a unit.

CAUTION: If the lifters and guide holder assembly are to be reused, they must me installed in their original location.

2. Install roller lifters and the lifter guide holder (2). Tighten bolt (1) to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
3. Install the cylinder head. Refer to **CYLINDER HEAD, INSTALLATION, 5.7L**.
4. Connect the negative battery cable.

CAUTION: To prevent damage to valve assemblies, do not run the engine above fast idle until all hydraulic lifters have filled with oil and have become quiet.

5. Start the engine and check for leaks.
6. Road test the vehicle.

RETAINER, CRANKSHAFT REAR OIL SEAL

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - REAR SEAL AREA LEAKS

The crankshaft rear oil seal is integral to the crankshaft rear oil seal retainer and cannot be serviced separately.

Since it is sometimes difficult to determine the source of an oil leak in the rear seal area of the engine, a more involved inspection is necessary. The following steps should be followed to help pinpoint the source of the leak.

If the leakage occurs at the crankshaft rear oil seal area:

1. Raise and support the vehicle.
2. Remove the transmission inspection/torque converter access cover.
3. Inspect the rear of the cylinder block for evidence of oil leakage, note the following:
   - Circular spray pattern generally indicates seal leakage or crankshaft damage.
   - Where leakage tends to run straight down, possible causes are a porous block, camshaft bore cup plugs, oil gallery pipe plugs, oil filter runoff, and main bearing cap to cylinder block mating surfaces. See appropriate Engine component service information for proper repair procedures of these items.
4. If no leaks are detected, pressurize the crankcase as outlined in **AIR LEAK DETECTION TEST METHOD**.

   CAUTION: Do not exceed 20.6 kPa (3 psi).

5. If the leak is not detected, very slowly turn the crankshaft and watch for leakage. If a leak is detected between the crankshaft and seal while slowly turning the crankshaft, it is possible the crankshaft seal surface is damaged. The seal area on the crankshaft could have minor nicks or scratches that can be polished out using an emery cloth.

   CAUTION: Use extreme caution when crankshaft polishing is necessary to remove minor nicks or scratches. The crankshaft seal flange is specially machined to complement the function of the rear oil seal.

6. For bubbles that remain steady with shaft rotation, no further inspection can be done. Refer to **RETAINER, CRANKSHAFT REAR OIL SEAL, REMOVAL, 5.7L**.

NOTE: **The crankshaft rear oil seal is integral to the crankshaft rear oil seal retainer and must be replaced as an assembly.**

NOTE: **The crankshaft rear oil seal retainer can not be reused after removal.**

NOTE: **This procedure can be performed in vehicle.**

1. Disconnect the negative battery cable.
2. On automatic transmission models, remove the flexplate. Refer to **FLEXPLATE, REMOVAL, 5.7L**.
3. On manual transmission models, remove the flywheel. Refer to **FLYWHEEL, REMOVAL** .
4. Remove the oil pan. Refer to **PAN, OIL, REMOVAL, 5.7L**.
5. Using the sequence shown in illustration, remove the rear oil seal retainer mounting bolts.
6. Carefully remove the retainer from the engine block.

STANDARD PROCEDURE - PISTON RING FITTING

PISTON RING END GAP

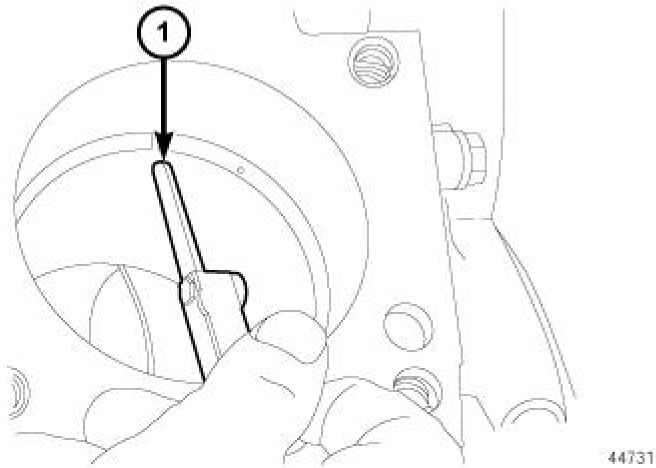

Fig. 166: Checking Piston Ring End Gap Using Feeler Gauge
Courtesy of CHRYSLER GROUP, LLC

NOTE: **Before reinstalling used rings or installing new rings, the ring clearances must be checked.**

1. Wipe the cylinder bore clean.
2. Insert the ring in the cylinder bore.

   NOTE: **The ring gap measurement must be made with the ring positioned at least 12 mm (0.472 inch.) from bottom of cylinder bore.**

3. Using a piston, to ensure that the ring is squared in the cylinder bore, slide the ring downward into the cylinder.
4. Using a feeler gauge check the ring end gap. Replace any rings not within specification.

PISTON RING SIDE CLEARANCE

NOTE: **Make sure the piston ring grooves are clean and free of nicks and burrs.**

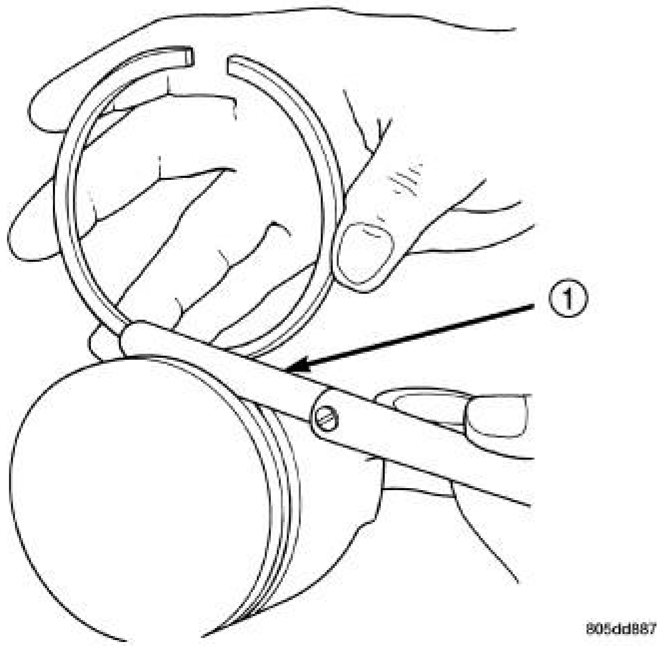

Fig. 167: Checking Piston Ring Grooves Clearances
Courtesy of CHRYSLER GROUP, LLC

1. Measure the ring side clearance as shown in illustration make sure the feeler gauge (1) fits snugly between the ring land and the ring. Replace any ring not within specification.
2. Rotate the ring around the piston, the ring must rotate in the groove with out binding.

PISTON RING INSTALLATION

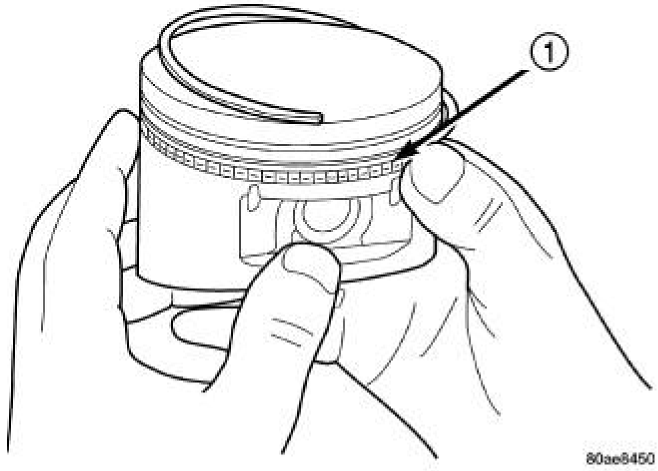

Fig. 168: Installing Piston Ring Side Rail
Courtesy of CHRYSLER GROUP, LLC

NOTE: **The No. 1 and No. 2 piston rings have a different cross section. Ensure No. 2 ring is installed with manufacturers I.D. mark (Dot) facing up, towards top of the piston.**

NOTE: **Piston rings are installed in the following order:**

- **Oil ring expander.**
- **Lower oil ring side rail.**
- **Upper oil ring side rail.**
- **No. 2 Intermediate piston ring.**
- **No. 1 Upper piston ring.**

1. Install the oil ring expander.
2. Install upper side rail by placing one end between the piston ring groove and the expander ring. Hold end firmly and press down the portion to be installed until side rail is in position. Repeat this step for the lower side rail.

NOTE: Install the piston rings so the gaps positioned as indicated with the piston viewed from the top.

NOTE: Staggering ring gap is important for oil control.

5. Install the oil expander so the ring gap is located in the (1) position.
6. Install the oil ring rails so the ring gap is located in the (2, 4) position.
7. Install the second compression ring so the ring gap is located in the (3) position.
8. Install the top compression so the ring gap is located in the (1) position.

ROD, PISTON AND CONNECTING

DESCRIPTION

DESCRIPTION

CAUTION: Do not use a metal stamp to mark connecting rods as damage may result, instead use ink or a scratch awl.

The pistons are made of a high strength aluminum alloy. Piston skirts are coated with a solid lubricant (MolykoteÂ®) to reduce friction and provide scuff resistance. The piston top ring groove and land is anodized. The connecting rods are made of forged powdered metal, with a fractured cap design.

STANDARD PROCEDURE

STANDARD PROCEDURE - PISTON FITTING

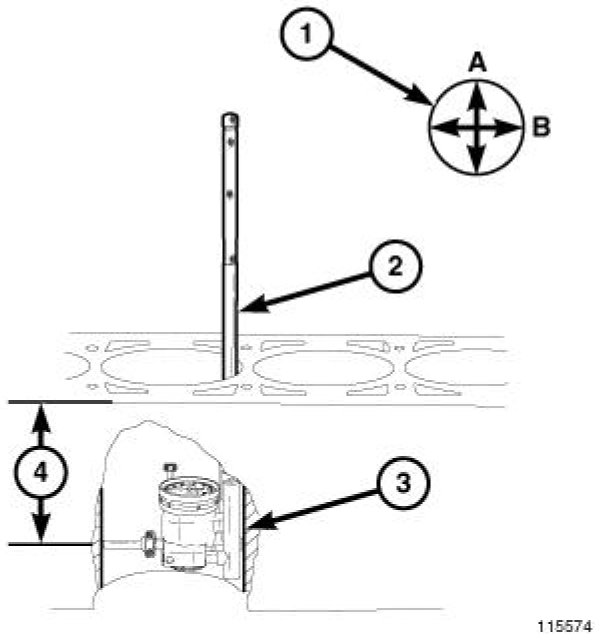

Fig. 171: Measuring Cylinder Bore Diameter
Courtesy of CHRYSLER GROUP, LLC

1. To correctly select the proper size piston, use Cylinder Indicator (special tool #C-119, Cylinder Indicator) (2) to measure the inside diameter of the cylinder bore (3). A cylinder bore gauge capable of reading in 0.003 mm (0.0001 in.) Increments is required. If a bore gauge is not available, do not use an inside micrometer.
2. Measure the inside diameter of the cylinder bore at a point 38.0 mm (1.5 inches) below the top of bore (4). Start perpendicular (across or at 90Â°) to the axis of the crankshaft at point A (1) and then take an additional bore reading 90Â° at point B (1).
3. The coated pistons will be serviced with the piston pin and connecting rod pre-assembled. The piston-rod assembly is specific for the left cylinder bank (odd numbered) and the right cylinder bank (even numbered) and must not be interchanged.

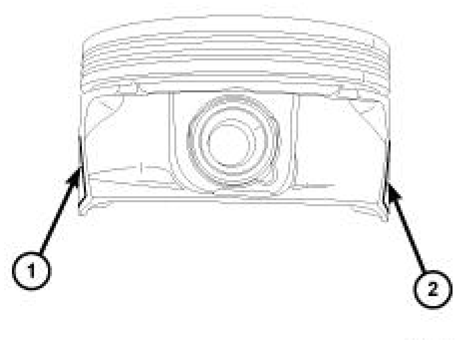

Fig. 172: Piston Diameter Measuring Points

4. Measure the piston diameter with a micrometer at points (1, 2).

REMOVAL

REMOVAL

1. Perform the fuel system pressure release procedure. Refer to **FUEL DELIVERY, GAS, STANDARD PROCEDURE** .
2. Disconnect and isolate the negative battery cable.
3. Remove the cylinder head(s). Refer to **CYLINDER HEAD, REMOVAL, 5.7L**.
4. Remove the oil pan. Refer to **PAN, OIL, REMOVAL, 5.7L**.
5. Remove support and lower the vehicle.
6. If necessary, remove the ridge on top of the cylinder bores with a reliable ridge reamer before removing the pistons from the cylinder block. **Be sure to keep the tops of the pistons covered during this operation.**

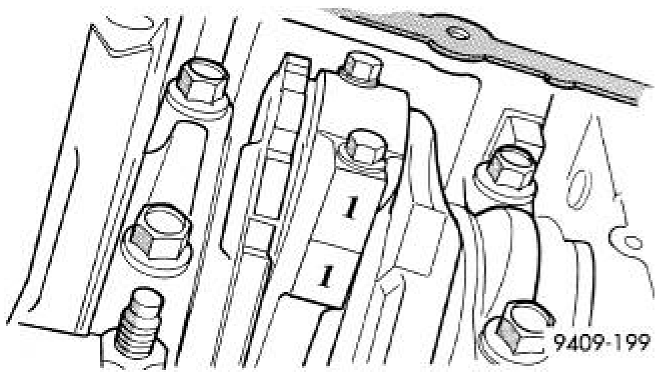

Fig. 173: Identifying Mark On Connecting Rod And Bearing Cap
Courtesy of CHRYSLER GROUP, LLC

CAUTION: **Do not use a number stamp or a punch to mark connecting rods or caps, as damage to connecting rods could occur.**

NOTE: **Connecting rods and bearing caps are not interchangeable and should be marked before removal to ensure correct reassembly.**

7. Raise and support the vehicle.
8. Mark the connecting rod and bearing cap positions using a permanent ink marker or scribe tool.

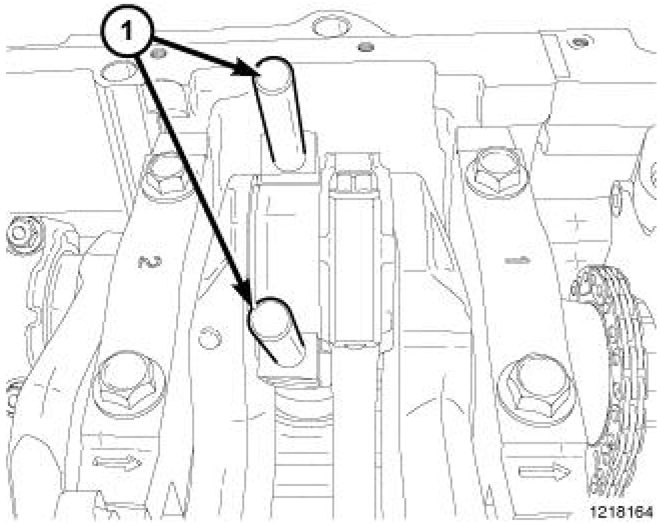

Fig. 174: Connecting Rod Guides
Courtesy of CHRYSLER GROUP, LLC

CAUTION: **Care must be taken not to damage the fractured rod and cap joint face surfaces, as engine damage may occur.**

CAUTION: **Care must be taken not to nick crankshaft journals, as engine damage may occur.**

NOTE: **Pistons and connecting rods assemblies must be removed from the top of cylinder block. When removing the piston and connecting rod assemblies from the engine, rotate the crankshaft so each connecting rod is centered in the cylinder bore.**

9. Remove the connecting rod cap, install the Connecting Rod Guides (special tool #8507, Guides, Connecting Rod) (1) and carefully remove the piston from the cylinder bore, repeat this procedure for each piston being removed.
10. Immediately after removing the piston and connecting rod, install the bearing cap on the mating connecting rod to prevent damage to the fractured cap and rod surfaces.
11. Carefully remove the piston rings from the piston(s), starting from the top ring down.

CLEANING

CLEANING

CAUTION: **DO NOT use a wire wheel or other abrasive cleaning devise to clean the pistons or connecting rods. The pistons have a Moly coating, this coating must not be damaged.**

1. Using a suitable cleaning solvent, clean the pistons in warm water and towel dry.
2. Use a wood or plastic scraper to clean the ring land grooves.

CAUTION: **Do not remove the piston pin from the piston and connecting rod assembly.**

INSPECTION

INSPECTION

Check the connecting rod journal for excessive wear, taper and scoring. Refer to **STANDARD PROCEDURE**.

Check the connecting rod for signs of twist or bending.

Check the piston for taper and elliptical shape before it is fitted into the cylinder bore. Refer to **STANDARD PROCEDURE**.

Check the piston for scoring or scraping marks in the piston skirts. Check the ring lands for cracks and/or deterioration.

INSTALLATION

INSTALLATION

NOTE:	**Before reinstalling used rings or installing new rings, the ring clearances must be checked.**

NOTE:	**Make sure the piston ring grooves are clean and free of nicks and burrs.**

1. Check piston ring clearance. Refer to **STANDARD PROCEDURE**.
2. Before installing piston and connecting rod assemblies into the bore, install the piston rings. Refer to **STANDARD PROCEDURE**.
3. Immerse the piston head and rings in clean engine oil and position a ring compressor over the piston and rings and tighten the ring compressor. **Ensure the position of rings do not change during this operation.**
4. Position the rod bearing (1) onto the connecting rod and lubricate bearing surface with clean engine oil.

6. The pistons are marked on the piston pin bore surface with an raised "F" or arrow on top of piston indicating installation position. This mark must be pointing toward the front of engine on both cylinder banks.
7. Wipe cylinder bore clean and lubricate with clean engine oil.
8. Rotate the crankshaft until the connecting rod journal is centered with the cylinder bore.
9. Insert the piston and rod assembly into the cylinder bore and carefully position the connecting rod over

the crankshaft journal.

10. Tap the piston down into the cylinder bore using a hammer handle while guiding the connecting rod into position on the rod journal.

11. Remove the Connecting Rod Guides (special tool #8507, Guides, Connecting Rod).
12. Wipe the connecting rod cap (1) clean and lubricate with clean engine oil and install the bearing (3).

NOTE: **The connecting rods and bearing caps are not interchangeable, line up the previously marked bearing caps and connecting rods to ensure assembly to their original location.**

13. Lubricate the bearing surfaces with clean engine oil and position the rod cap in place.

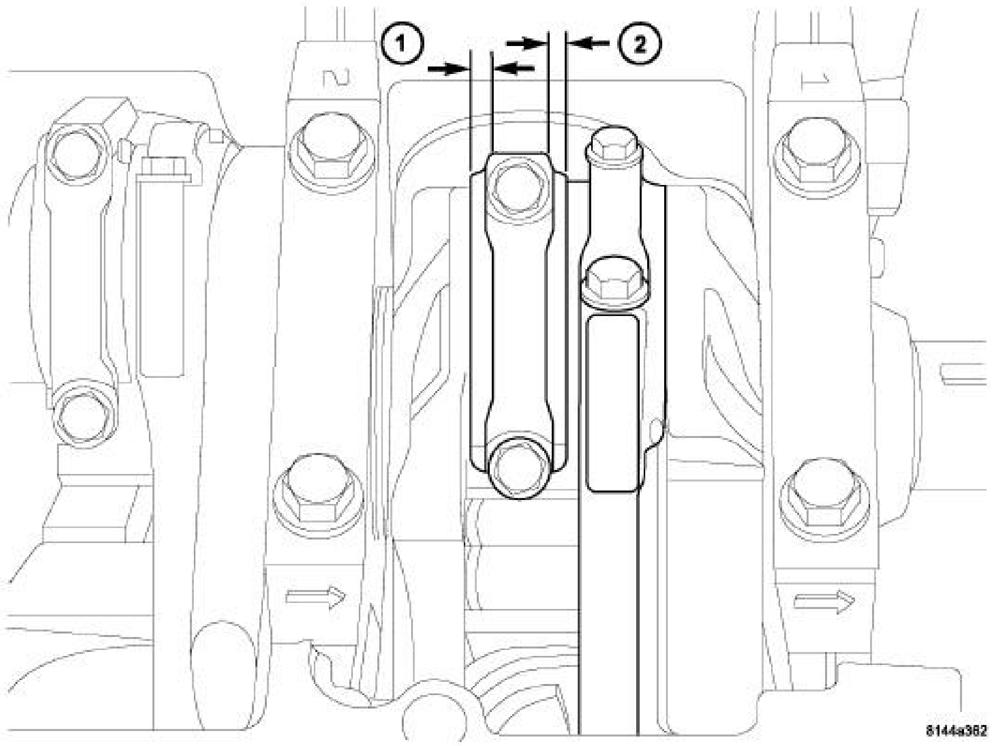

Fig. 179: Identifying Connecting Rod Proper Installation

CAUTION: **When installing the connecting rods, make sure the wide side of the connecting rod faces the crankshaft and the narrow sides face each other.**

CAUTION: **Always replace the connecting rod bolts whenever they are loosened or removed.**

14. Lubricate the **NEW** rod cap bolts with clean engine oil, install and tighten to the proper specification. Refer to TORQUE SPECIFICATIONS.
15. Install the new oil pan gasket/windage tray and oil pan. Refer to PAN, OIL, INSTALLATION, 5.7L.
16. Install the cylinder head(s). Refer to CYLINDER HEAD, INSTALLATION, 5.7L.
17. Connect the negative battery cable.

SOLENOID, MULTIPLE DISPLACEMENT

DESCRIPTION

DESCRIPTION

The Multi Displacement System (MDS) selectively deactivates cylinders 1, 4, 6, and 7, to improve fuel economy. It has two modes of operation:

- 8 cylinders for acceleration and heavy loads.

- 4 cylinders for cruising and city traffic.

The main components of the Multi Displacement System are:

- Unique MDS camshaft.
- Deactivating roller tappets.
- 4 control valves/solenoids.
- control valve/solenoid wiring harness.
- oil temp sensor.

OPERATION

OPERATION

Cylinder Deactivation

- Trap an exhaust charge from a normal combustion event
- Normal combustion event
- Don't open the exhaust valve
- Don't open the intake valve
- Piston is an air spring
- Cylinders deactivated in firing sequence
- Deactivating roller tappets

Cylinder Reactivation

- Open the exhaust valve
- Empty the cylinder
- Open the intake valve
- Normal combustion event
- Cylinders reactivated in firing sequence
- Reactivating roller tappets

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - MDS SOLENOID

The Multi-Displacement System (MDS) has the following detectable issues:

- solenoid circuit
- fail to deactivate a cylinder(s)
- fail to reactivate a cylinder(s)
- low oil pressure

CONDITION	POSSIBLE CAUSES	CORRECTION
MDS does not activate	1. Low oil pressure.	1. Check for proper oil pressure.

CONDITION	POSSIBLE CAUSES	CORRECTION
	2. Bad oil temperature sensor.	2. Replace the oil temperature sensor.
-	3. Malfunctioning MDS solenoid.	3. Replace the solenoid.
-	4. Malfunctioning MDS tappet.	4. Replace tappet (s).
MDS does not deactivate	1. Low oil pressure.	1. Check or proper oil pressure.
	2. Bad oil temperature sensor.	2. Replace the oil temp sensor.
-	3. Malfunctioning MDS solenoid.	3. Replace the solenoid.
-	4. Malfunctioning MDS tappet.	4. Replace tappet(s).

LUBRICATION

DESCRIPTION

DESCRIPTION

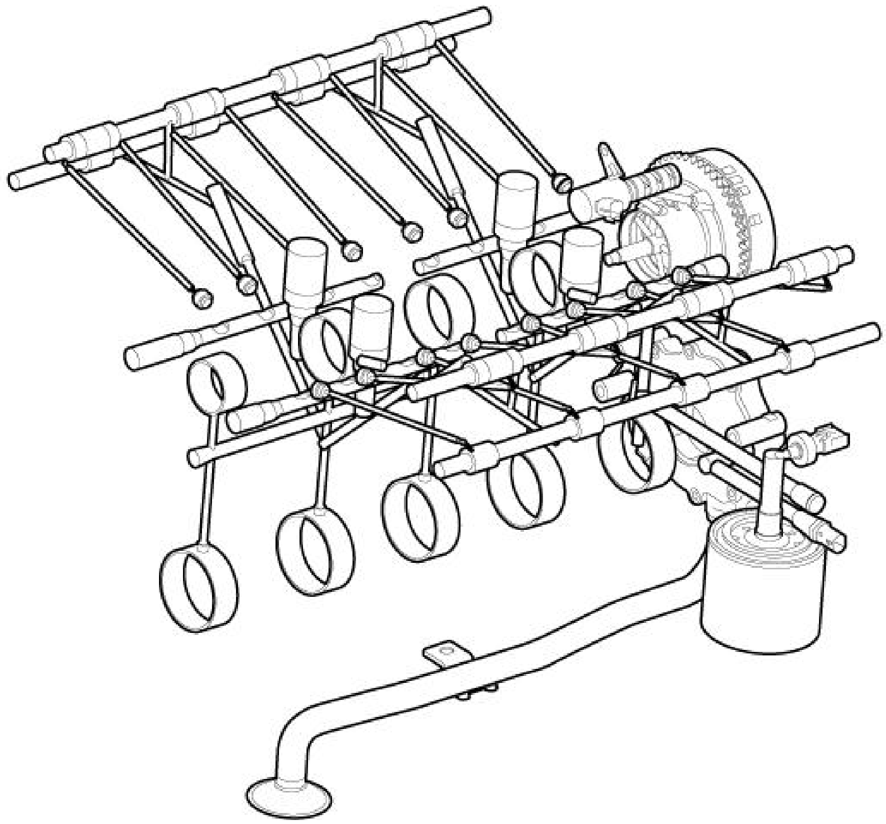

Fig. 210: 5.7L MDS Lubrication System

The 5.7L MDS lubrication system is a full flow filtration pressure feed type.

DIAGNOSIS AND TESTING

CHECKING ENGINE OIL PRESSURE

1. Remove the oil pressure sending unit and install gauge assembly (special tool #C-3292A, Gauge, Pressure).
2. Run the engine until thermostat opens.
3. Oil Pressure:
   - Curb Idle-25 kPa (4 psi) minimum
   - 3000 RPM-170 - 758 kPa (25 - 110 psi)
4. If oil pressure is 0 at idle, shut off engine. Check for a clogged oil pick-up screen or a pressure relief valve stuck open.

ENGINE OIL LEAK

Begin with a thorough visual inspection of the engine, particularly at the area of the suspected leak. If an oil leak source is not readily identifiable, the following steps should be followed:

1. Do not clean or degrease the engine at this time because some solvents may cause rubber to swell, temporarily stopping the leak.
2. Add an oil soluble dye (use as recommended by manufacturer). Start the engine and let idle for approximately 15 minutes. Check the oil dipstick to make sure the dye is thoroughly mixed as indicated

with a bright yellow color under a black light.

3. Using a black light, inspect the entire engine for fluorescent dye, particularly at the suspected area of the oil leak. If the oil leak is found and identified, repair per service information instructions.
4. If dye is not observed, drive the vehicle at various speeds for approximately 24 km (15 miles), and repeat inspection.

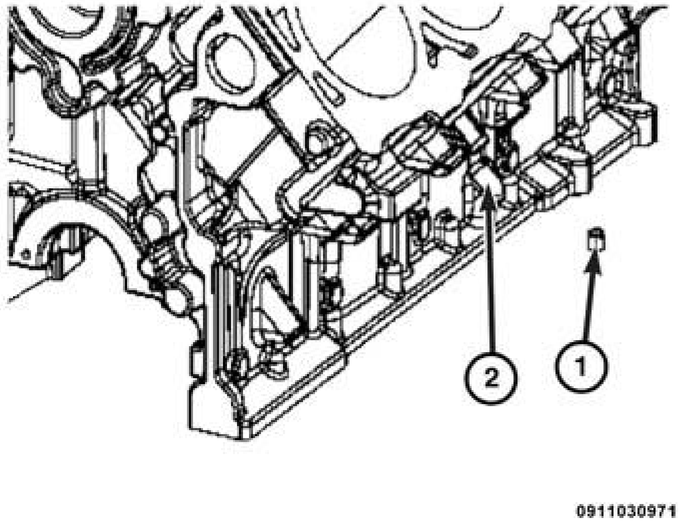

Fig. 211: Engine Oil Pan Plug Component Location
Courtesy of CHRYSLER GROUP, LLC

NOTE: **If the oil indicator tube is located in the engine oil pan. A plug (1) is inserted into the hole on the engine block (2). Validation of the plug is required when the engine block has been replaced.**

AIR LEAK DETECTION TEST METHOD

1. Remove the Positive Crankcase Ventilation (PCV) valve from the Integrated Air-Fuel Module (IAFM). Cap or plug the PCV valve grommet.
2. Attach an air hose with a pressure gauge and regulator to the dipstick tube.

CAUTION: **Do not subject the engine assembly to more than 20.6 kPa (3 PSI) of test pressure.**

3. Gradually apply air pressure from 1 psi to 2.5 psi maximum while applying soapy water at the suspected source. Adjust the regulator to the suitable test pressure that provide the best bubbles which will pinpoint the leak source. If the oil leak is detected and identified, repair per service information procedures.
4. If the leakage occurs at the rear oil seal area, refer to **INSPECTION FOR REAR SEAL AREA LEAKS**.
5. If no leaks are detected, turn off the air supply and remove the air hose and all plugs and caps. Install the PCV valve.
6. Clean the oil off the suspect oil leak area using a suitable solvent. Drive the vehicle at various speeds approximately 24 km (15 miles). Inspect the engine for signs of an oil leak by using a black light.

INSPECTION FOR REAR SEAL AREA LEAKS

Since it is sometimes difficult to determine the source of an oil leak in the rear seal area of the engine, a more involved inspection is necessary. The following steps should be followed to help pinpoint the source of the leak.

If the leakage occurs at the crankshaft rear oil seal area:

1. Disconnect the battery.
2. Raise and support the vehicle. Refer to **HOISTING, STANDARD PROCEDURE** .
3. Remove torque converter or clutch housing cover and inspect rear of block for evidence of oil. Use a black light to check for the oil leak:
    a. Circular spray pattern generally indicates seal leakage or crankshaft damage.
    b. Where leakage tends to run straight down, possible causes are a porous block, distributor seal, camshaft bore cup plugs oil gallery pipe plugs, oil filter runoff, and main bearing cap to cylinder block mating surfaces.
4. If no leaks are detected, pressurize the crankcase as outlined in **AIR LEAK DETECTION TEST METHOD**.

    CAUTION: Do not exceed 20.6 kPa (3 psi).

5. If the leak is not detected, very slowly turn the crankshaft and watch for leakage. If a leak is detected between the crankshaft and seal while slowly turning the crankshaft, it is possible the crankshaft seal surface is damaged. The seal area on the crankshaft could have minor nicks or scratches that can be polished out with emery cloth.

    CAUTION: Use extreme caution when crankshaft polishing is necessary to remove minor nicks and scratches. The crankshaft seal flange is especially machined to complement the function of the rear oil seal.

6. For bubbles that remain steady with shaft rotation, no further inspection can be done until disassembled.

SOLENOID, VARIABLE VALVE TIMING (VVTS), EXHAUST

DESCRIPTION

DESCRIPTION

The 5.7L engine is equipped with Variable Valve Timing (VVT). This system uses an variable valve control valve to direct oil pressure into the camshaft phaser assembly. The camshaft phaser assembly advances and/or retards camshaft timing to improve engine performance, mid-range torque, idle quality, fuel economy, and reduce emissions. The VVTS is located under the intake manifold.

OPERATION

OPERATION

The Variable Valve Timing (VVT) assembly is actuated with engine oil pressure. The oil flow to the VVT assemblies are controlled by an Variable Valve Timing Solenoid (VVTS). The VVTS consist of a Pulse Width Modulated (PWM) solenoid and a spool valve. The PCM actuates the VVTS to control oil flow through the spool valve into the VVT assemblies. The VVT assembly consists of a rotor, stator, and sprocket. The stator is

connected to the timing chain through the sprocket. The rotor is connected to the camshaft. Oil flow in to the VVT assembly rotates the rotor with respect to the stator, thus rotating the exhaust camshaft with respect to the timing chain and intake camshaft. An infinitely variable valve timing position can be achieved within the limits of the hardware. The CMP monitors the position of the camshaft with respect to the crankshaft and provides feedback to the PCM.

1. Lubricate oil filter gasket with engine oil.
2. Install the oil filter (1) until the gasket seal makes contact with the sealing surface. Tighten the oil filter to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
3. Install the belly pan. Refer to **BELLY PAN, INSTALLATION** or **BELLY PAN, ENGINE, INSTALLATION** .
4. Fill crankcase with specified type and amount of engine oil. Refer to **CAPACITIES AND RECOMMENDED FLUIDS, SPECIFICATIONS** .
5. Start engine and inspect for oil leaks.

OIL

STANDARD PROCEDURE

STANDARD PROCEDURE - ENGINE OIL SERVICE

The engine oil level indicator is located at the left hand of the engine on the 5.7L engines.

CRANKCASE OIL LEVEL INSPECTION

CAUTION: Do not overfill crankcase with engine oil, pressure loss or oil foaming can result.

Inspect engine oil level approximately every 800 kilometers (500 miles). Unless the engine has exhibited loss of oil pressure, run the engine for about ten minutes before checking oil level. Checking engine oil level on a cold engine is not accurate.

To ensure proper lubrication of an engine, the engine oil must be maintained at an acceptable level. The acceptable levels are indicated between the ADD and SAFE marks on the engine oil dipstick.

It is recommended that the engine oil level should be checked when the engine is at operating temperature.

1. Position vehicle on level surface.
2. With engine OFF, allow approximately five minutes for oil to settle to bottom of crankcase, remove engine oil dipstick.
3. Wipe dipstick clean.
4. Install dipstick and verify it is seated in the tube.
5. Remove dipstick, with handle held above the tip, take oil level reading.
6. Verify the oil level to be at the top of the "SAFE" range +/- 1/4 of the total distance of the range.
7. Add oil only if level is below the ADD mark on dipstick.

ENGINE OIL CHANGE

Change engine oil at mileage and time intervals described in Maintenance Schedules. Refer to **MAINTENANCE SCHEDULES, DESCRIPTION** .

Run engine until achieving normal operating temperature.

1. Remove oil fill cap.
2. Raise and support vehicle. Refer to **HOISTING, STANDARD PROCEDURE** .

7. Place a suitable drain pan under oil filter (1) and remove the oil filter.
8. Clean the gasket sealing surface and insure the old gasket is removed.
9. Lubricate the oil filter (1) gasket seal with clean engine oil.
10. Install the oil filter (1) until the gasket seal makes contact with the sealing surface. Tighten the oil filter to

the proper specification. Refer to **TORQUE SPECIFICATIONS**.

11. Install the belly pan and securely tighten bolts (1).
12. Remove support and lower vehicle.
13. Fill crankcase with specified type and amount of engine oil. Refer to **CAPACITIES AND RECOMMENDED FLUIDS, SPECIFICATIONS** .
14. Install oil fill cap.
15. Start engine and inspect for leaks.
16. Stop engine and inspect oil level.

NOTE: **Care should be exercised when disposing used engine oil after it has been drained from a vehicle engine. Refer to the WARNING at beginning of this section.**

CLEANING

CLEANING

1. Wash all parts in a suitable solvent.

INSPECTION

INSPECTION

CAUTION: The oil pump pressure relief valve and spring should not be removed from the oil pump. If these components are disassembled and or removed from the pump the entire oil pump assembly must be replaced.

1. Remove the pump cover.

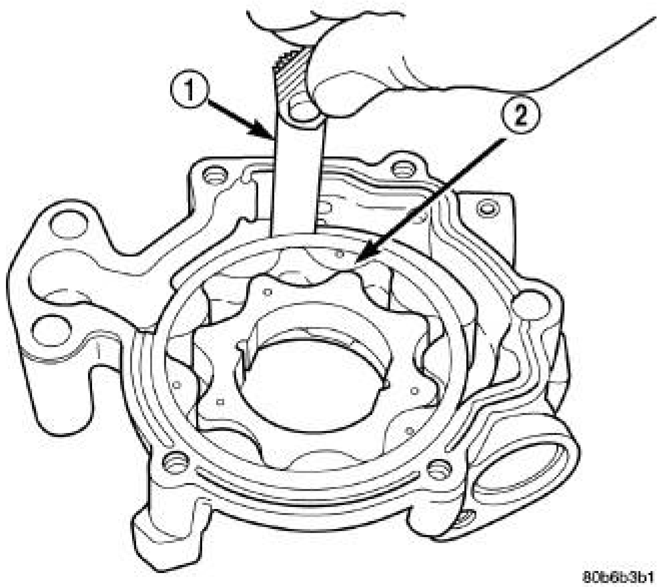

Fig. 238: Measuring Outer Rotor Clearance in Housing
Courtesy of CHRYSLER GROUP, LLC

2. Clean all parts thoroughly. Mating surface of the oil pump housing should be smooth. If the pump cover is scratched or grooved the oil pump assembly should be replaced.
3. Slide outer rotor into the body of the oil pump. Press the outer rotor to one side of the oil pump body and measure clearance between the outer rotor (2) and the body. If the measurement is 0.235 mm (0.009 in.) or more the oil pump assembly must be replaced.

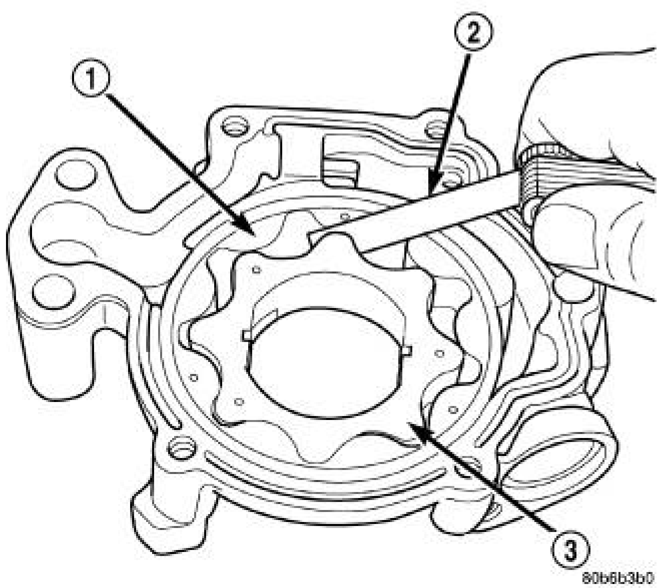

Fig. 239: Measuring Clearance Between Rotors

4. Install the inner rotor into the oil pump body. Measure the clearance between the inner (3) and outer rotors (1). If the clearance between the rotors is 0.150 mm (0.006 in.) or more the oil pump assembly must be replaced.

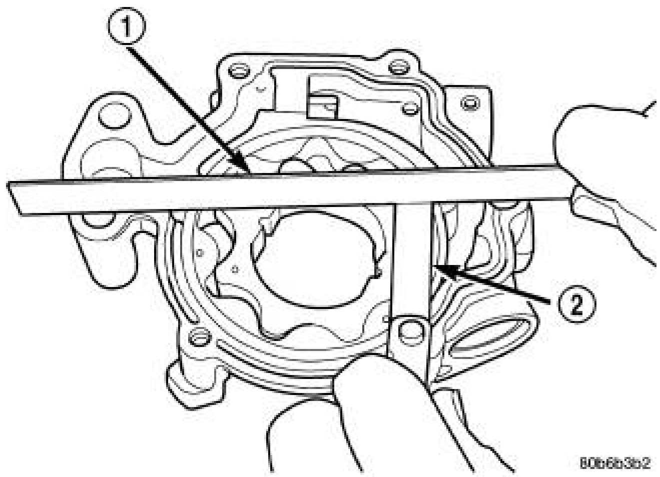

Fig. 240: Measuring Clearance Between Outer Rotor And Body
Courtesy of CHRYSLER GROUP, LLC

5. Place a straight edge (1) across the body of the oil pump (between the bolt holes), if a feeler gauge (2) of 0.095 mm (0.003 in.) or greater can be inserted between the straightedge and the rotors, the pump must be replaced.
6. Reinstall the pump cover. Tighten fasteners to the proper specification. Refer to **TORQUE SPECIFICATIONS**.

NOTE: **The 5.7 Oil pump is serviced as an assembly. In the event the oil pump is not functioning or out of specification, it must be replaced as an assembly.**

2. Using the sequence shown in illustration, tighten the oil pump bolts to 28 N.m (21 ft. lbs.).

3. Install the timing cover. Refer to **COVER(S), ENGINE TIMING, INSTALLATION, 5.7L**.
4. Install the oil pan. Refer to **PAN, OIL, INSTALLATION, 5.7L**.

SENSOR, OIL PRESSURE

DESCRIPTION

DESCRIPTION

The oil pressure sensor uses the following three circuits:

- Signal circuit to the Powertrain Control Module (PCM)
- Sensor ground circuit through the PCM
- 5 volt reference circuit from the PCM

The oil pressure sensor returns a voltage signal back to the PCM with reference to oil pressure. Ground for the sensor is supplied by the PCM.

The oil pressure sensor is located on the right side of the engine block. The sensor screws into the engines main oil gallery.

REMOVAL

REMOVAL

1. Disconnect and isolate the negative battery cable.

SENSOR, OIL TEMPERATURE

DESCRIPTION

DESCRIPTION

The oil temperature sensor uses the following two circuits:

- Signal circuit to the Powertrain Control Module (PCM)
- Ground circuit from the PCM

The oil temperature sensor is a Negative Thermal Coefficient (NTC) sensor. The resistance of the sensor changes as oil temperature changes. This results in different output voltages back to the PCM.

The oil temperature sensor is located on the right side of the engine block.

MANIFOLDS

MANIFOLD, EXHAUST

DESCRIPTION

DESCRIPTION

The exhaust manifolds are log style with a patented flow enhancing design to maximize performance. The exhaust manifolds are made of high silicon molybdenum cast iron. A multi-layer stainless steel exhaust manifold gasket is used to improve sealing to the cylinder head. The exhaust manifolds are covered by a three layer laminated heat shield for thermal protection and noise reduction. The heat shields are fastened with a torque prevailing nut that is backed off slightly to allow for the thermal expansion of the exhaust manifold, with the exception of the nut, which also secures the oil dipstick tube bracket. That nut should not be backed off.

OPERATION

OPERATION

The exhaust manifolds collect the engine exhaust exiting the combustion chambers, then channels the exhaust gases to the exhaust pipes attached to the manifolds.

CLEANING

CLEANING

Clean mating surfaces on cylinder head and manifold. Wash with solvent and blow dry with compressed air.

INSPECTION

INSPECTION

Inspect manifold for cracks.

Inspect mating surfaces of manifold for flatness with a straight edge. Gasket surfaces must be flat within 0.2 mm per 300 mm (0.008 inch per foot).

MANIFOLD, INTAKE

DESCRIPTION

DESCRIPTION

CAUTION: If the engine has experienced a catastrophic failure, THE INTAKE MANIFOLD MUST BE REPLACED!

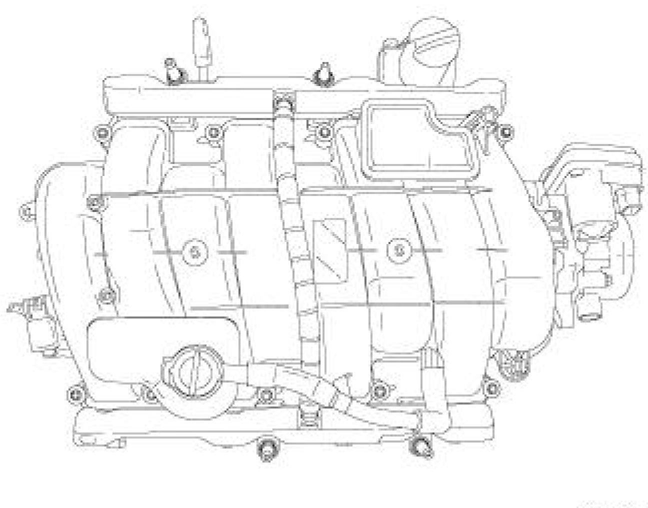

Fig. 255: Intake Manifold
Courtesy of CHRYSLER GROUP, LLC

The intake manifold is made of a composite material with the runners tuned to give the best balance of power and torque. The manifold uses a single plane sealing system and separate Positive Crankcase Ventilation (PCV) port seals to prevent leaks. The screws connecting the manifold to the head use a thread lock patch, and must be replaced when the manifold is serviced.

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - INTAKE MANIFOLD LEAKAGE

An intake manifold air leak is characterized by lower than normal manifold vacuum. Also, one or more cylinders may not be functioning.

WARNING: Use extreme caution when the engine is operating. Do not stand in a direct line with the fan. Do not put your hands near the pulleys, belts or the fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.

1. Start the engine.
2. Spray a small stream of water at the suspected leak area.
3. If a change in RPM is observed the area of the suspected leak has been found.
4. Repair as required.

REMOVAL

REMOVAL

1. Perform the fuel system pressure release procedure. Refer to **FUEL DELIVERY, GAS, STANDARD PROCEDURE** .
2. Disconnect and isolate the negative battery cable.
3. Remove the air cleaner body. Refer to **BODY, AIR CLEANER, REMOVAL, 5.7L**.
4. Disconnect the fuel supply line. Refer to **FITTING, QUICK CONNECT, STANDARD PROCEDURE** .
5. Disconnect the brake booster hose and the EVAP purge line.

6. Disconnect the following components wire harness connectors:
   - Manifold Absolute Pressure (MAP) Sensor
   - Fuel Injectors
   - Electronic Throttle Control (ETC).
7. Using the sequence shown in illustration, remove bolts and the intake manifold.

CLEANING

CLEANING

NOTE: **There is NO approved repair procedure for the intake manifold. If severe damage is found during inspection, the intake manifold must be replaced.**

Before installing the intake manifold thoroughly clean the mating surfaces. Use a suitable cleaning solvent, then air dry.

INSPECTION

INSPECTION

1. Inspect the intake sealing surface for cracks, nicks and distortion.
2. Inspect the intake manifold vacuum hose fittings for looseness or blockage.

INSTALLATION

INSTALLATION

NOTE: **The intake manifold seals (1, 3) may be used again, provided no cuts, tears, or deformation have occurred.**

1. Inspect the intake manifold seals and replace if necessary.

NOTE: **If reinstalling the original manifold, apply MoparÃ® Lock & Seal Adhesive to the intake manifold bolts. Not required when installing a new manifold.**

2. If required, apply MoparÃ® Lock & Seal Adhesive to the intake manifold bolts.
3. Position the intake manifold (2).

4. Using the sequence shown in illustration, tighten the bolts to 12 N.m (9 ft. lbs.).
5. Connect the fuel supply line. Refer to FITTING, QUICK CONNECT, STANDARD PROCEDURE .

6. Connect the brake booster hose and the EVAP purge line.
7. Connect the following components wire harness connectors:
    - Manifold Absolute Pressure (MAP) Sensor
    - Fuel Injectors
    - Electronic Throttle Control (ETC).
8. Install the air cleaner body. Refer to **BODY, AIR CLEANER, INSTALLATION, 5.7L**.
9. Connect the negative battery cable.
10. Start the engine and check for leaks.

14. Remove the camshaft phaser retaining bolt (1) and remove the timing chain with the camshaft phaser and crankshaft sprocket.

NOTE: **Do not rotate the crankshaft or camshaft after timing chain removal. The 5.7L engine has zero skipped tooth clearance. Catastrophic engine damage will result if the proper camshaft and crankshaft positions and not established during assembly.**

INSTALLATION

INSTALLATION

CAUTION: **This is a Zero-Tolerance engine. Failure to properly align the timing chain to the timing gears will cause severe engine damage. It is imperative that the Timing**

Marks shown in illustration in the subsequent steps be properly aligned during assembly.

19. **NOTE:** **The timing mark located on the camshaft phaser must be properly centered between the dual marks on the timing chain while at the 12 O'clock position (1). The timing mark located on the crankshaft must be properly aligned with the single mark on the timing chain while at the 6 O'clock position (2).**

20. Verify that the chains are operating smoothly. The chain must be replaced if:
    - Any kinks
    - Signs of binding
    - Damage to the links
    - Signs of wear or stretching

The timing chain tensioner is a spring loaded design. It consists of two chain guide shoes. One shoe is fixed in place and the other is spring loaded to keep tension on the chain.

OPERATION

OPERATION

The timing chain tension is maintained by routing the timing chain through the tensioner assembly. A nylon shoe presses on the timing chain maintaining the correct chain tension.

DESCRIPTION

DESCRIPTION

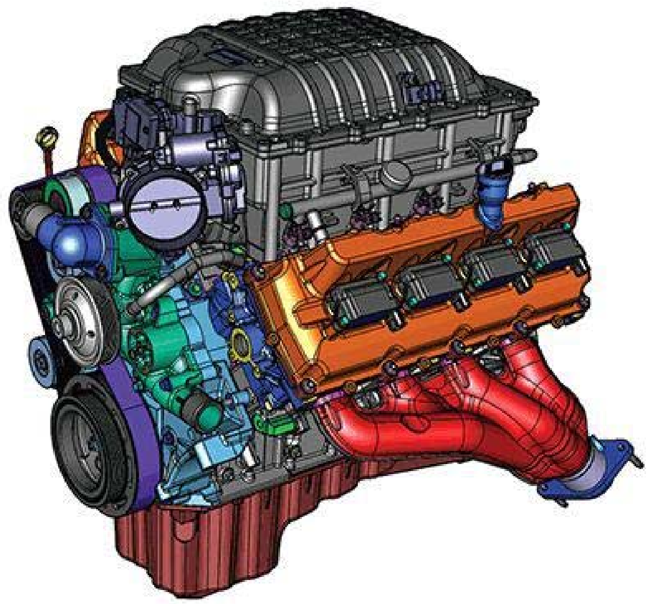

Fig. 1: 6.2L HEMIÂ® Eight-Cylinder SRT High Performance Engine
Courtesy of CHRYSLER GROUP, LLC

The supercharged 6.2L HEMI eight-cylinder SRT high performance engine is a 90Â° V-Type, deep skirt, lightweight cast iron block with forged aluminum pistons, forged steel crankshaft, aluminum heads, single cam, overhead valves, and hydraulic roller lifters. The heads incorporate splayed valves with a hemispherical style combustion chamber and dual spark plugs. The cylinders are numbered from front to rear; 1, 3, 5, 7 on the left bank and 2, 4, 6, 8 on the right bank. The firing order is 1-8-4-3-6-5-7-2.

DIAGNOSIS AND TESTING

CYLINDER COMBUSTION PRESSURE LEAKAGE

The combustion pressure leakage test provides an accurate means for determining engine condition.

Combustion pressure leakage testing will detect:

- Exhaust and intake valve leaks (improper seating)
- Leaks between adjacent cylinders or into water jacket
- Any causes for combustion pressure loss

1. Check the coolant level and fill as required. DO NOT install the radiator cap.

2. Start and operate the engine until it attains normal operating temperature.
3. Turn the engine OFF.
4. Remove one spark plug per cylinder.
5. Remove the oil filler cap.
6. Remove the air cleaner hose.
7. **Calibrate the tester according to the manufacturer's instructions.** The shop air source for testing should maintain a regulated air pressure at 552 kPa (80 psi).
8. Perform the test procedures on each cylinder according to the tester manufacturer's instructions. Set the piston of the cylinder to be tested at TDC compression.
9. During the testing, listen for pressurized air escaping through the throttle body, tailpipe and oil filler cap opening. Check for bubbles in the radiator coolant.

All gauge pressure indications should be equal, with **no more** than 25% leakage.

FOR EXAMPLE: Input air at 552 kPa (80 psi), the primary gauge factory set at 207 kPa (30 psi) input pressure. The secondary gauge should have no more than 176 kPa (25.5 psi) loss, when connected to the cylinder.

Refer to CYLINDER COMBUSTION PRESSURE LEAKAGE DIAGNOSIS CHART.

CYLINDER COMBUSTION PRESSURE LEAKAGE DIAGNOSIS CHART

CONDITION	POSSIBLE CAUSE	CORRECTION
Air escapes through the throttle body	Intake valve bent, burnt, or not seated properly.	Inspect valve and valve seat. Reface or replace, as necessary. Inspect valve springs. Replace as necessary.
Air escapes through the tailpipe	Exhaust valve bent, burnt, or not seated properly.	Inspect valve and valve seat. Reface or replace, as necessary. Inspect valve springs. Replace as necessary.
Air escapes through the radiator	Cylinder head gasket leaking or cracked in cylinder head or engine block.	Remove cylinder head and inspect. Replace cylinder head gasket, cylinder head or engine block as necessary.
More than 50% leakage from adjacent cylinders	Cylinder head gasket leaking or crack in cylinder head or engine block between adjacent cylinders.	Remove cylinder head and inspect. Replace cylinder head gasket, cylinder head or engine block as necessary.
More than 25% leakage and air escapes through the oil filler cap opening only	Stuck or broken piston rings; cracked piston; worn rings or cylinder wall.	Remove cylinder head and inspect for broken rings or piston. Measure ring gap and cylinder diameter, taper and out-of-round. Replace defective part as necessary.

	9. Oil pump cover warped or cracked.	9. Install new oil pump.
	10. Faulty or missing piston cooling jets.	10. Replace piston cooling jets.

CONDITION	POSSIBLE CAUSES	CORRECTION
OIL LEAKS	1. Misaligned or deteriorated gaskets.	1. Replace gasket.
	2. Loose fastener or broken or porous metal part.	2. Tighten, repair or replace the part.
	3. Front or rear crankshaft oil seal leaking.	3. Replace seal.
	4. Leaking oil gallery plug or cup plug.	4. Remove and reseal threaded plug. Replace cup style plug.
EXCESSIVE OIL CONSUMPTION OR SPARK PLUGS OIL FOULED	1. PCV System malfunction.	1. Refer to **VALVE, POSITIVE CRANKCASE VENTILATION (PCV), REMOVAL** .
	2. Defective valve stem seal(s).	2. Repair or replace seal(s).
	3. Worn or broken piston rings.	3. Hone cylinder bores. Install new rings.
	4. Scuffed pistons/cylinder walls.	4. Hone cylinder bores and replace pistons as required.
	5. Carbon in oil control ring groove.	5. Remove rings and de-carbon piston.
	6. Worn valve guides.	6. Inspect/replace valve guides as necessary.
	7. Piston rings fitted too tightly in grooves.	7. Remove rings and check ring end gap and side clearance. Replace if necessary.

Lifter Purge Guideline

1. Warm engine to standard idle conditions.

NOTE: **Engine noise may be in the form of a clicking, chatter, or clattering noise.**

2. Listen to the engine for 30 to 60 seconds with the hood up and the engine cover removed.
3. If noise is present, de-aeration of the lifters is required.
4. Run the engine between 2000 and 3000 RPM for three to five minutes.
5. Return the engine to standard idle speed for 30 to 60 seconds.
6. Evaluate noise. If noise is present, repeat the run an additional 4 cycles.

NOTE: **The standard drive cycle will be about 10-15 miles of non-stop, combined highway and city driving.**

7. If noise is present, take the vehicle on a standard drive cycle.
8. Evaluate the noise. If noise present, follow standard service procedure for lifter repairs or noise conditions.
9. Evaluate the lifters for sponginess, check valve defects, and clearance.

ENGINE LUBRICATION DIAGNOSTIC TABLE

CONDITION	POSSIBLE CAUSES	CORRECTION
OIL LEAKS	1. Gaskets and O-rings • Misaligned or damaged • Loose fasteners, broken or porous metal parts 2. Crankshaft rear seal 3. Crankshaft seal flange damaged 4. Oil pan flange cracked 5. Front cover seal damaged/misaligned 6. Damaged vibration damper 7. Crankshaft rear flange microporosity	1. Verify condition • Replace as necessary • Tighten fasteners, repair or replace metal parts 2. Replace as necessary 3. Polish or replace crankshaft 4. Replace oil pan 5. Replace seal 6. Polish or replace damper 7. Replace crankshaft
OIL PRESSURE DROP	1. Low oil level 2. Faulty oil pressure sending unit 3. Low oil pressure 4. Clogged oil filter 5. Worn oil pump 6. Thin or diluted oil 7. Excessive bearing clearance 8. OIL PUMPING AT RINGS; SPARK PLUGS FOULING	1. Worn or damaged rings 2. Carbon in oil ring slots 3. Incorrect ring size installed 4. Worn valve guides 5. Leaking intake gasket 6. Leaking valve guide seals	1. Hone cylinder bores and replace rings 2. Replace rings 3. Replace rings 4. Ream guides and replace valves 5. Replace intake gaskets 6. Replace valve guide seals

OIL CONSUMPTION TEST AND DIAGNOSIS

The following diagnostic procedures are used to determine the source of excessive internal oil consumption, these procedures and tests apply to vehicles with 50, 000 miles or less.

NOTE: **Engine oil consumption may be greater than normal during engine break-in.**

Repairs should be delayed until vehicle has been driven at least 7, 500 miles.

Severe service (high ambient temperature, short trips, heavy loading, trailer towing, taxi, off-road, or law enforcement use) may result in greater oil consumption than normal.

Sustained high speed driving and high engine RPM operation may result in increased oil consumption.

Failure to comply with the recommended oil type and viscosity rating, as outlined in the owner's manual, may impact oil economy as well as fuel economy.

Oil consumption may increase with vehicle age and mileage due to normal engine wear.

NOTE: **Because a few drops of external oil leakage per mile can quickly account for the loss of one quart of oil in a few hundred miles, verify that no external engine oil leaks are present.**

- **Oil leakage is not the same as oil consumption and all external leakage must be eliminated before any action can be taken to verify and correct oil consumption complaints.**
- **Verify that the engine has the correct oil level dipstick and dipstick tube installed.**
- **Verify that the engine is not being run in an overfilled condition. Check the oil level 15 minutes after a hot shutdown with the vehicle parked on a level surface. In no case should the level be above MAX or the FULL mark on the dipstick.**

OIL CONSUMPTION TEST

1. Check the oil level at least 15 minutes after a hot shutdown.
2. If the oil level is low, top off with the proper viscosity and API service level engine oil. Add one bottle of MOPARĀ® 4-In-1 Leak Detection Dye into the engine oil.
3. Tamper proof the oil pan drain plug, oil filter, dipstick and oil fill cap.
4. Record the vehicle mileage.
5. Instruct the customer to drive the vehicle as usual.
6. Ask the customer to return to the servicing dealer after accumulating 500 miles, Check the oil level at least 15 minutes after a hot shutdown. If the oil level is half way between the "FULL" and "ADD" mark continue with the next step.
7. Using a black light, recheck for any external engine oil leaks, repair as necessary, if no external engine oil leaks are present, continue with oil consumption diagnosis.

OIL CONSUMPTION DIAGNOSIS

1. Check the Positive Crankcase Ventilation (PCV) system. Make sure the system is not restricted and the PCV valve has the correct part number and correct vacuum source (18-20 in. Hg at idle below 3000 ft. above sea level is considered normal).
2. Perform a cylinder compression test and cylinder leak down test using the standard leak down gauge following manufacturers suggested best practices.

   NOTE: **Verify the spark plugs are not oil saturated. If the spark plugs are oil saturated and compression is good it can be assumed the valve seals or**

valve guides are at fault.

3. If one or more cylinders have more than 15% leak down further engine tear down and inspection will be required.

TOP 18 REASONS THAT MAY LEAD TO ENGINE OIL CONSUMPTION

1. **Tapered and Out-of-Round Cylinders**

   The increased piston clearances permit the pistons to rock in the worn cylinders. While tilted momentarily, an abnormally large volume of oil is permitted to enter on one side of the piston. The rings, also tilted in the cylinder, permit oil to enter on one side. Upon reversal of the piston on each stroke, some of this oil is passed into the combustion chamber.

2. **Distorted Cylinders**

   This may be caused by unequal heat distribution or unequal tightening of cylinder head bolts. This condition presents a surface which the rings may not be able to follow completely. In this case, there may be areas where the rings will not remove all of the excess oil. When combustion takes place, this oil will be burned and cause high oil consumption.

3. **Improper operation of the PCV system**

   The main purpose of the Positive Crankcase Ventilation (PCV) valve is to recirculate blow-by gases back from the crankcase area through the engine to consume unburned hydrocarbons. The PCV system usually has a one way check valve and a make up air source. The system uses rubber hoses that route crankcase blow by gases to the intake manifold. Vacuum within the engine intake manifold pulls the blow by gases out of the crankcase into the combustion chamber along with the regular intake air and fuel mixture.

   The PCV system can become clogged with sludge and varnish deposits and trap blow by gases in the crankcase. This degrades the oil, promoting additional formation of deposit material. If left uncorrected, the result is plugged oil rings, oil consumption, rapid ring wear due to sludge buildup, ruptured gaskets and seals due to crankcase pressurization.

4. **Worn Piston Ring Grooves**

   For piston rings to form a good seal, the sides of the ring grooves must be true and flat - not flared or shouldered. Piston rings in tapered or irregular grooves will not seal properly and, consequently, oil will pass around behind the rings into the combustion chamber.

5. **Worn, Broken or Stuck Piston Rings**

   When piston rings are broken, worn or stuck to such an extent that the correct tension and clearances are not maintained, this will allow oil to be drawn into the combustion chamber on the intake stroke and hot gases of combustion to be blown down the cylinder past the piston on the power stroke. All of these conditions will result in burning and carbon build up of the oil on the cylinders, pistons and rings.

6. **Cracked or Broken Ring Lands**

   Cracked or broken ring lands prevent the rings from seating completely on their sides and cause oil

pumping. This condition will lead to serious damage to the cylinders as well as complete destruction of the pistons and rings. Cracked or broken ring lands cannot be corrected by any means other than piston replacement.

7. **Worn Valve Stems and Guides**

   When wear has taken place on valve stems and valve guides, the vacuum in the intake manifold will draw oil and oil vapor between the intake valve stems and guides into the intake manifold and then into the cylinder where it will be burned.

8. **Bent or Misaligned Connecting Rods**

   Bent or misaligned connecting rods will not allow the pistons to ride straight in the cylinders. This will prevent the pistons and rings from forming a proper seal with the cylinder walls and promote oil consumption. In addition, it is possible that a bearing in a bent connect rod will not have uniform clearance on the connecting rod wrist pin. Under these conditions, the bearing will wear rapidly and throw off an excessive amount of oil into the cylinder.

9. **Fuel Dilution**

   If raw fuel is allowed to enter the lubrication system, the oil will become thinner and more volatile and will result in higher oil consumption. The following conditions will lead to higher oil consumption;

   - Excess fuel can enter and mix with the oil via a leaking fuel injector
   - Gasoline contaminated with diesel fuel
   - Restricted air intake
   - Excessive idling

10. **Contaminated Cooling Systems**

    Corrosion, rust, scale, sediment or other formations in the water jacket and radiator will prevent a cooling system from extracting heat efficiently. This is likely to cause cylinder distortion thus leading to higher oil consumption.

11. **Oil Viscosity**

    The use of oil with a viscosity that is too light may result in high oil consumption. Refer to the vehicle owner's manual for the proper oil viscosity to be used under specific driving conditions and ambient temperatures.

12. **Dirty Engine Oil**

    Failure to change the oil and filter at proper intervals may cause the oil to be so dirty that it will promote accumulation of sludge and varnish and restrict oil passages in the piston rings and pistons. This will increase oil consumption; dirty oil by nature is also consumed at a higher rate than clean oil.

13. **Crankcase Overfull**

    Due to an error in inserting the oil dip stick so that it does not come to a seat on its shoulder, a low reading may be obtained. Additional oil may be added to make the reading appear normal with the stick

in this incorrect position which will actually make the oil level too high. If the oil level is so high that the lower ends of the connecting rods touch the oil in the oil pan excessive quantities of oil will be thrown on the cylinder walls and some of it will work its way up into the combustion chamber.

14. **Excessively High Oil Pressure**

    A faulty oil pressure relief valve may cause the oil pressure to be too high. The result will be that the engine will be flooded with an abnormally large amount of oil in a manner similar to that which occurs with worn bearings. This condition may also cause the oil filter to burst.

15. **Aftermarket Performance Chips and Modification**

    Increasing performance through the use of performance/power enhancement products to a stock or factory engine will increase the chance of excessive oil consumption.

16. **Lugging Engine**

    Lugging is running the engine at a lower RPM in a condition where a higher RPM (more power/torque) should be implemented. Especially susceptible on vehicles equipped with a manual transmission. This driving habit causes more stress loading on the piston and can lead to increases in engine oil consumption.

17. **Turbocharged Engines**

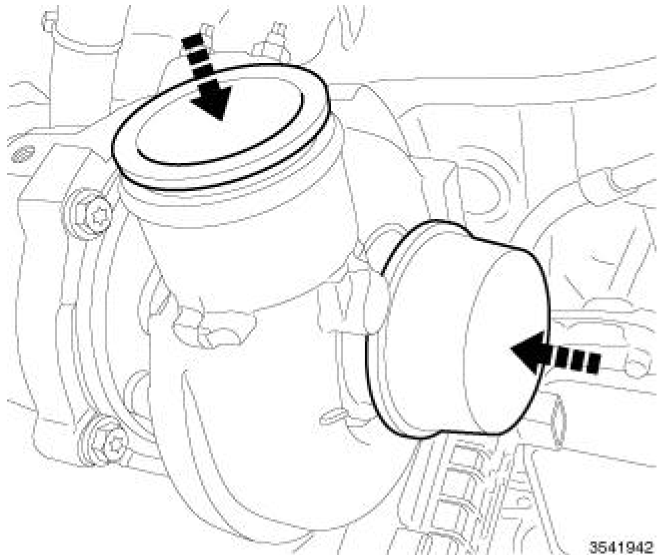
    There is a possibility for PCV "push-over" due to higher crankcase pressure (as compared to naturally aspirated engines) which is normal for turbocharged engines. This condition causes varying amounts of engine oil to enter the intake manifold, charge air cooler and associated plumbing to and from the charge air cooler, also a leaking turbocharger seal will draw oil into the combustion chamber where it will burn (blue smoke from the tail pipe may be present) and form carbon deposits which contribute to further oil consumption as they interfere with proper engine function.

18. **Restricted Air Intake**

    Excessive restriction in the air intake system will increase engine vacuum and can increase oil consumption. An extremely dirty air filter would be one example of this situation.

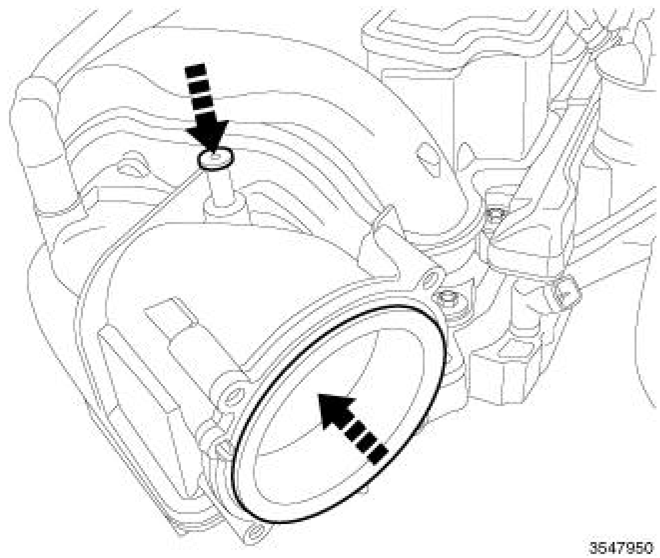
STANDARD PROCEDURE

DUST COVERS AND CAPS



[Fig. 2: Covers/Caps]
Courtesy of CHRYSLER GROUP, LLC

To avoid the possibility of dust, dirt, moisture and other foreign debris being introduced to the engine during service, cover or cap all openings when hoses and tubes are removed.



[Fig. 3: Opening Cover]
Courtesy of CHRYSLER GROUP, LLC

Covers installed over openings will reduce the possibility of foreign materials to entering the engine systems. Using miller tool Universal Protective Cap Set (special tool #10368, Set, Universal Protective Cap), select the appropriate cover needed for the procedure.

ENGINE GASKET SURFACE PREPARATION

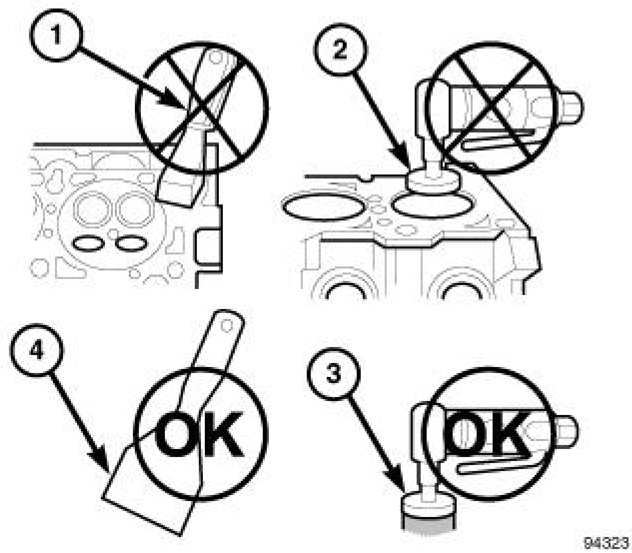


Fig. 4: Proper Tool Usage For Surface Preparation
Courtesy of CHRYSLER GROUP, LLC

To ensure engine gasket sealing, proper surface preparation must be performed, especially with the use of aluminum engine components and multi-layer steel cylinder head gaskets.

Never use the following to clean gasket surfaces:

- Metal scraper (1).
- Abrasive pad or paper to clean cylinder block and head.
- High speed power tool with an abrasive pad or a wire brush (2).

NOTE: Multi-Layer Steel (MLS) head gaskets require a scratch free sealing surface.

Only use the following for cleaning gasket surfaces:

- Solvent or a commercially available gasket remover
- Plastic or wood scraper (4).
- Drill motor with 3M Roloc™ Bristle Disc (3), white is used for the aluminum heads and yellow is used for the iron block.

CAUTION: Excessive pressure or high RPM (beyond the recommended speed), can damage the sealing surfaces. The mild (white, 120 grit) bristle disc is recommended. If necessary, the medium (yellow, 80 grit) bristle disc may be used on cast iron surfaces with care.

REPAIR DAMAGED OR WORN THREADS

CAUTION: Always maintain the original center line when drilling and/or tapping holes.

Damaged or worn threads can be repaired. Essentially, this repair consists of:

- Drilling out worn or damaged threads

- Tapping the hole with a special Heli-CoilÂ® Tap or equivalent
- Installing a Heli-CoilÂ® insert into the tapped hole to bring the hole back to its original thread size

HYDROSTATIC LOCK

CAUTION: Do not attempt to run engine. Severe damage could occur.

When an engine is suspected of hydrostatic lock (regardless of what caused the problem), follow the steps below.

1. Disconnect and isolate the negative battery cable.
2. Lift the engine cover retaining grommets off the ball studs and remove the engine cover.
3. Place a shop towel around the fuel supply line quick connect fitting to catch any fuel that may be under pressure, then disconnect the fuel supply line. Refer to **FITTING, QUICK CONNECT, STANDARD PROCEDURE** .
4. Loosen the air duct retaining clamp at the throttle body.
5. Disconnect the intake air temperature sensor electrical connector.
6. Remove the makeup air hose at the air cleaner housing.
7. Remove the air cleaner housing retaining bolt.
8. While lifting up the air cleaner housing, slide the air duct off the throttle body and remove the air cleaner housing from the vehicle.
9. Inspect the air duct, air cleaner housing and the intake manifold to make sure the system is dry and clear of any foreign material.
10. Place a shop towel around the spark plugs to catch any fluid that may possibly be under pressure in the cylinder head.
11. Remove the spark plugs. Refer to **SPARK PLUG, REMOVAL** .
12. With the spark plugs removed, rotate the crankshaft using a breaker bar and socket.
13. Identify the fluid in the cylinders (coolant, fuel, oil, etc.).
14. Make sure all fluid has been removed from the cylinders.
15. Repair engine or components as necessary to prevent this problem from occurring again.
16. Squirt a small amount of engine oil into the cylinders to lubricate the walls. This will help prevent engine damage on restart.
17. Install new spark plugs. Refer to **SPARK PLUG, INSTALLATION** .
18. Perform the Engine Oil Service procedure. Refer to **STANDARD PROCEDURE**.
19. Connect negative battery cable.
20. Start the engine and check for leaks.

REMOVAL

REMOVAL

CAUTION: If the engine encounters a catastrophic failure, the engine oil cooler and lines must be replaced or damage to the new engine and/or components could result.

1. Raise and support the vehicle. Refer to **HOISTING, STANDARD PROCEDURE** .
2. Drain the cooling system. Refer to **STANDARD PROCEDURE** .
3. Drain the engine oil. Refer to **STANDARD PROCEDURE**.
4. Remove the supercharger assembly. Refer to **SUPERCHARGER, REMOVAL**.
5. Remove the cooling fan. Refer to **FAN, COOLING, REMOVAL** .

NOTE: The power steering lines do not need to be removed from the pump. Position pump to the side.

6. Remove the power steering pump. Refer to **PUMP, REMOVAL** .
7. Remove the A/C compressor. Refer to **COMPRESSOR, A/C, REMOVAL** .

NOTE: Left side shown in illustration, right side similar.

8. Remove both left/right engine mount heat shield (4) retaining nuts (3) and remove the heat shields.
9. Remove both left/right engine mount to frame retaining bolts (2).

10. Disconnect the transmission oil cooler lines from their retainers at the oil pan.
11. Remove the lower radiator hose.

40. Using a suitable jack, support the transmission.

NOTE: **Do not use air tools to install engine lift fixture.**

41. Install the (special tool #8984B, Fixture, Engine Lifting) (1) and (special tool #8984-UPD, Adapter, Engine Lift) (3).

42. Using a suitable engine hoist, separate the engine from the transmission and remove the engine from the engine compartment.
43. Secure the engine onto a suitable engine stand.

INSTALLATION

INSTALLATION

CAUTION: If the engine encounters a catastrophic failure, the engine oil cooler and lines must be replaced or damage to the new engine and/or components could result.

NOTE: Do not use air tools to install the (special tool #8984B, Fixture, Engine Lifting).

1. Install the engine lift fixture (1) (special tool #8984B, Fixture, Engine Lifting) and adapter (special tool #8984-UPD, Adapter, Engine Lift) (3).
2. Using a suitable engine hoist, lower the engine into the engine compartment.
3. Automatic transmission equipped vehicles, align the engine with the transmission.
4. Install two transmission bell housing to engine block bolts finger tight.
5. Lower the engine assembly until the engine mounts rest in the engine cradle crossmember.

NOTE: **Left side shown in illustration, right side similar.**

6. Align the engine mounts, install both left/right engine mount to frame retaining bolts (2) and tighten to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
7. Position both left and right engine mount heat shields (4), install the retaining nuts (3) and tighten to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
8. Remove the engine hoist and the jack supporting the transmission.
9. For manual transmission equipped vehicles, install the transmission. Refer to **INSTALLATION** . Then proceed to step 19.
10. For automatic transmission equipped vehicles, follow steps 11-18.
11. Raise and support the vehicle. Refer to **HOISTING, STANDARD PROCEDURE** .
12. Carefully engage transmission to engine block dowels until converter hub is seated in crankshaft. Verify that no wires, or the transmission vent hose, have become trapped between the engine block and the transmission.
13. Install two bolts to attach the transmission to the engine.

46. Position the ignition coil electrical harness and connect all ignition wire harness connectors (1).
47. Install the pressurized coolant bottle. Refer to **BOTTLE, PRESSURIZED COOLANT, INSTALLATION** .
48. Position the wire harness and secure to the right hand inner fender panel.
49. Install the cooling fan. Refer to **FAN, COOLING, INSTALLATION** .
50. Install the supercharger assembly. Refer to **SUPERCHARGER, INSTALLATION**.
51. Fill the crankcase with the specified type and amount of engine oil. Refer to **CAPACITIES AND RECOMMENDED FLUIDS, SPECIFICATIONS** .
52. Fill the cooling system with the specified type and amount of engine coolant. Refer to **STANDARD PROCEDURE** .
53. Connect the negative battery cable.
54. Perform the Refrigerant System Charge procedure. Refer to **PLUMBING, STANDARD PROCEDURE** .
55. Start the engine and inspect for leaks.

NOTE: **The Cam/Crank Variation Relearn procedure must be performed using the scan tool anytime there has been a repair/replacement made to a powertrain system. For example: flywheel, valvetrain, camshaft and/or crankshaft sensors or components.**

Courtesy of CHRYSLER GROUP, LLC

1. Remove the air cleaner housing cover retaining screws (3).
2. Disconnect the Mass Air Flow (MAF) sensor wire harness connector (2).
3. Loosen the clamp (1) to remove air cleaner housing cover if necessary.

4. Lift the air cleaner housing cover while separating the locating tabs from the housing.
5. Remove the air cleaner element from the housing.
6. Clean the inside of air cleaner housing before replacing element.

INSTALLATION

INSTALLATION

Courtesy of CHRYSLER GROUP, LLC

1. Install the air cleaner element into the housing.
2. Align the air cleaner housing cover locating tabs into the housing while lowering the cover into position.
3. If removed, insert air cleaner housing cover into the air inlet tube and tighten the clamp (1) to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
4. Install the air cleaner housing cover retaining screws (3) and tighten to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
5. Connect the Mass Air Flow (MAF) sensor wire harness connector (2).

BODY, AIR CLEANER

REMOVAL

REMOVAL

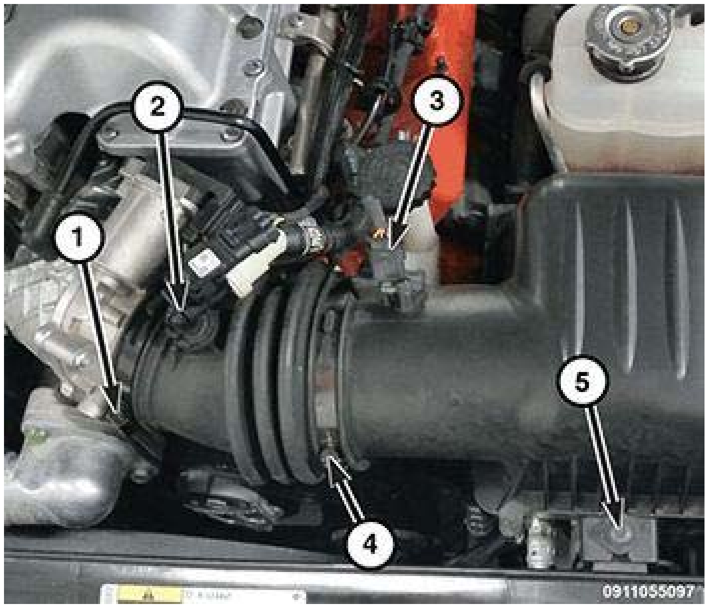

Fig. 38: Air Inlet Tube Retaining Clamps, Makeup Air Sensor, MAF Sensor & Air Cleaner Housing Retaining Bolt
Courtesy of CHRYSLER GROUP, LLC

1. Disconnect and isolate the negative battery cable.
2. Loosen the air inlet tube retaining clamp (1) at the throttle body.
3. Disconnect the makeup air sensor wire harness connector.
4. Disconnect the makeup air hose and remove the makeup air sensor (2) from the air inlet duct.
5. Disconnect the Mass Air Flow (MAF) sensor (3).
6. Remove the air cleaner housing retaining bolt (5).
7. While lifting up the air cleaner housing, slide the air duct off the throttle body and remove the air cleaner housing from the vehicle.

NOTE: **There is a secondary air inlet duct to the front of the air cleaner housing, behind the headlamp, this must be disengaged for removal.**

8. If necessary, remove the air inlet tube clamp (4) from the air cleaner housing to remove the air inlet tube.

INSTALLATION

INSTALLATION

1. If removed, insert the air inlet tube onto the air cleaner housing and tighten the clamp (4) to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
2. While sliding the air duct onto the throttle body, lower the air cleaner housing into position, then align the air inlet and the locating pin on the bottom of the housing.
3. Align the secondary air inlet tube behind the headlamp, there are indexing tabs for orientation.
4. Install the air cleaner housing retaining bolt (5) and tighten to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
5. Install the makeup air sensor (2) into the air inlet tube and connect the makeup air hose.
6. Connect the makeup air sensor wire harness connector.
7. Connect the Mass Air Flow (MAF) sensor wire harness connector (3).
8. Position the air inlet tube retaining clamp (1) at the throttle body and tighten to the proper specification. Refer to **TORQUE SPECIFICATIONS**.

CYLINDER HEAD

OPERATION

OPERATION

The cylinder head closes the combustion chamber allowing the pistons to compress the air fuel mixture to the correct ratio for ignition. The valves located in the cylinder head open and close to either allow clean air into the combustion chamber or to allow the exhaust gases out, depending on the stroke of the engine.

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - CYLINDER HEAD GASKET FAILURE

A cylinder head gasket leak can be located between adjacent cylinders or between a cylinder and the adjacent

water jacket.

Possible indications of the cylinder head gasket leaking between adjacent cylinders are:

- Loss of engine power
- Engine misfiring
- Poor fuel economy

Possible indications of the cylinder head gasket leaking between a cylinder and an adjacent water jacket are:

- Engine overheating
- Loss of coolant
- Excessive steam (white smoke) emitting from exhaust
- Coolant foaming

CYLINDER-TO-CYLINDER LEAKAGE TEST

To determine if an engine cylinder head gasket is leaking between adjacent cylinders, perform a Cylinder Compression Pressure Test. An engine cylinder head gasket leaking between adjacent cylinders will result in approximately a 50-70% reduction in compression pressure.

CYLINDER-TO-WATER JACKET LEAKAGE TEST

WARNING: Use extreme caution when the engine is operating with coolant pressure cap removed. Failure to follow this warning may result in serious or fatal injury.

VISUAL TEST METHOD

With the engine cool, remove the coolant pressure cap. Start the engine and allow it to warm up until thermostat opens.

If a large combustion/compression pressure leak exists, bubbles will be visible in the coolant.

COOLING SYSTEM TESTER METHOD

WARNING: With cooling system tester in place, pressure will build up fast. Excessive pressure built up, by continuous engine operation, must be released to a safe pressure level. Never permit pressure to exceed 138 kPa (20 psi). Failure to follow this warning may result in serious or fatal injury.

Install Cooling System Tester (special tool #7700, Tester, Cooling System) or equivalent to pressure cap neck. Start the engine and observe the tester's pressure gauge. If gauge pulsates with every power stroke of a cylinder a combustion pressure leak is evident.

CHEMICAL TEST METHOD

Combustion leaks into the cooling system can also be checked by using Bloc-Chek Kit (special tool #C-3685-A, Bloc-Chek Kit) or equivalent. Perform test following the procedures supplied with the tool kit.

REMOVAL

REMOVAL

1. Perform the fuel system pressure release procedure. Refer to **FUEL DELIVERY, GAS, STANDARD PROCEDURE** .
2. Disconnect and isolate the negative battery cable.
3. Remove the supercharger assembly. Refer to **SUPERCHARGER, REMOVAL**.
4. Remove the catalytic converters. Refer to **CONVERTER, CATALYTIC, REMOVAL** .
5. Remove the power steering pump. Refer to **PUMP, REMOVAL** .

NOTE: It is not necessary to remove the power steering hoses.

6. Remove the rocker arms and push rods. Refer to **ROCKER ARM, VALVE, REMOVAL**.

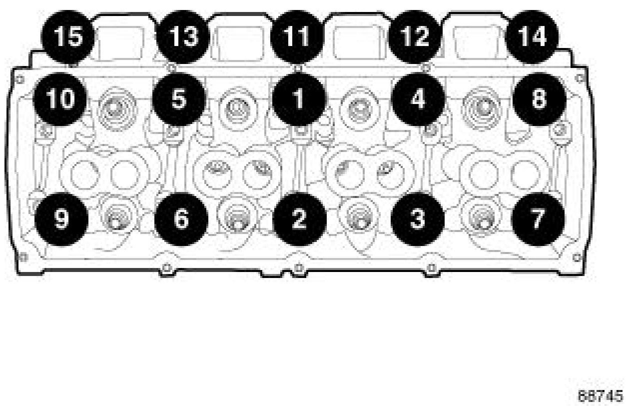

Fig. 40: Cylinder Head Bolt Removal & Tightening Sequence

10. If necessary, remove the exhaust manifold bolts using the sequence shown in illustration, starting at eight and going backwards.

CLEANING

CLEANING

Clean all surfaces of the cylinder block and cylinder heads.

Clean the cylinder block front and rear gasket surfaces using a suitable solvent.

INSPECTION

INSPECTION

1. Inspect the cylinder head for out-of-flatness using a straightedge and a feeler gauge. If tolerances exceed 0.0508 mm (0.002 in.) replace the cylinder head.
2. Inspect the valve seats for damage. Service the valve seats as necessary.
3. Inspect the valve guides for wear, cracks or looseness. If either condition exist, replace the cylinder head.
4. Inspect the push rods. Replace worn or bent push rods.
5. Inspect the rocker arm, push rod cups and pallets where they contact the valve tips. Any worn parts should be replaced with a new rocker shaft assembly.
6. Inspect the cylinder head bolts.

INSTALLATION

INSTALLATION

NOTE: **Left side shown in illustration, right side similar.**

1. If removed, using a new exhaust manifold gasket, position the exhaust manifold and install the retaining bolts finger tight.
2. Using the sequence shown in illustration, tighten the exhaust manifold retaining bolts to the proper specification. Refer to **TORQUE SPECIFICATIONS**.

NOTE: **The cylinder head gaskets are not interchangeable between left and right sides. They are marked "T" for top, "B" for bottom, "L" for left side and "R" for right side.**

3. Clean all sealing surfaces of the engine block and the cylinder head(s) (2).

NOTE: **Rotate crankshaft 45Ā° so that all pistons are 1/2 the way down the cylinder bore to avoid piston to valve contact.**

4. Position the new cylinder head gasket(s) (1) onto the engine block.
5. Position the cylinder head(s) (2) onto the engine block.
6. Install the cylinder head bolts finger tight.

7. Using the sequence below, tighten the retaining bolts.
    a. Using the sequence shown in illustration, tighten bolts 1-10 to 34 N.m (25 ft. lbs.).
    b. Using the sequence shown in illustration, tighten bolts 11-15 to 20 N.m (15 ft. lbs.).
    c. Using the sequence shown in illustration, tighten bolts 1-10 to 54 N.m (40 ft. lbs.).
    d. Using the sequence shown in illustration, verify bolts 11-15 are 20 N.m (15 ft. lbs.).
    e. Using the sequence shown in illustration, tighten bolts 1-10 to 61 N.m (45 ft. lbs.).
    f. Using the sequence shown in illustration, rotate bolts 1-10 an additional 90 degrees.
    g. Using the sequence shown in illustration, tighten bolts 11-15 to 28 N.m (21 ft. lbs.).
8. Install the push rods and rocker arms. Refer to **ROCKER ARM, VALVE, INSTALLATION**.
9. Install the power steering pump. Refer to **PUMP, INSTALLATION** .
10. Install the catalytic converters. Refer to **CONVERTER, CATALYTIC, INSTALLATION** .
11. Lower the vehicle.
12. Install the supercharger assembly. Refer to **SUPERCHARGER, INSTALLATION**.
13. Fill cooling system. Refer to **STANDARD PROCEDURE** .

NOTE: **Evacuating or purging air from the charge air cooling system must be done with the use of a pressurized air operated vacuum generator.**

14. Connect the negative battery cable (1).
15. Start engine check for leaks.

COVER(S), CYLINDER HEAD

REMOVAL

REMOVAL

1. Disconnect and isolate the negative battery cable.
2. Remove the ignition coils. Refer to **COIL, IGNITION, REMOVAL** .

CAUTION: **Do not use harsh cleaners to clean the cylinder head covers. Severe damage to covers may occur.**

CAUTION: **Do not allow other components including the wire harness to rest on or against the engine cylinder head cover. Prolonged contact with other objects may wear a hole in the cylinder head cover.**

NOTE: **The cylinder head cover gasket may be used again, provided no cuts, tears, or deformation have occurred.**

1. Clean the cylinder head cover (1) and the sealing surface of the cylinder head (2). Inspect the cylinder head cover gasket and the coil tower gaskets, replace if necessary.
2. Install the cylinder head cover and hand start all fasteners.

3. Using the sequence shown in illustration, loosen the rocker shaft assemblies.

CAUTION: The rocker shaft assemblies are not interchangeable between intake and exhaust. The intake rocker arms are marked with an "I".

4. Remove the rocker shaft assemblies. Note the location for reassembly.

CAUTION: The longer pushrods are for the exhaust side, and the shorter pushrods are for intake side.

5. Remove the push rods. Note the push rod location for reassembly.

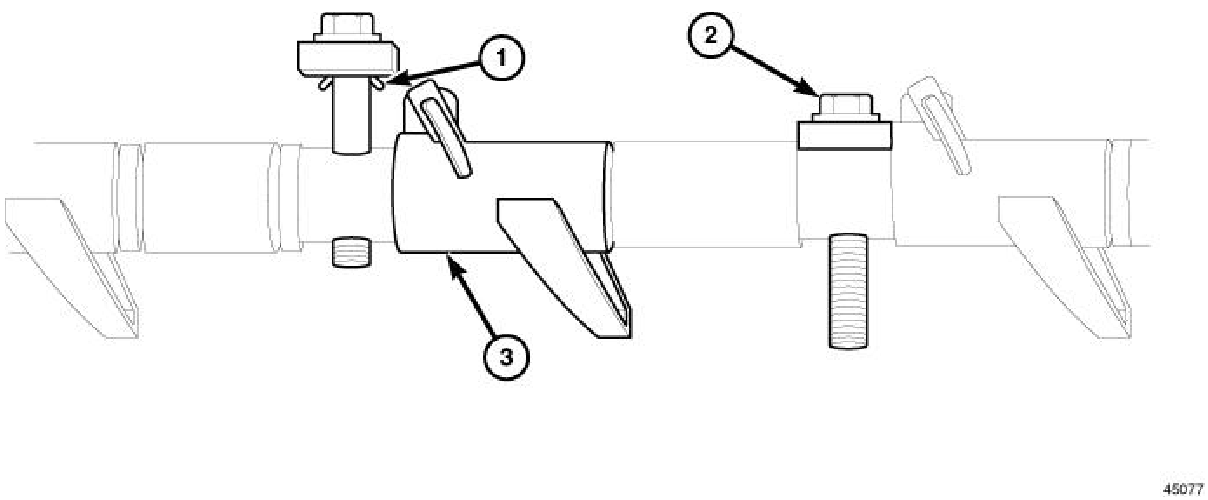
CAUTION: The longer pushrods are for the exhaust side, and the shorter pushrods are for intake side.

1. Install the push rods in the same order as removed.
2. Install the Push Rod Retainer (special tool #9070, Retainer, Push Rod) (1).



[Fig. 54: Rocker Arm Retainers]
Courtesy of CHRYSLER GROUP, LLC

CAUTION: Ensure the retainers (1) and rocker arms (3) are not overlapped when torquing bolts.

CAUTION: Verify the push rods are installed into the rocker arms (3) and lifters

correctly while installing the rocker shaft assembly. Recheck after the rocker shaft assembly has been torqued to specification.

3. Install the rocker shaft assemblies in the same order as removed.

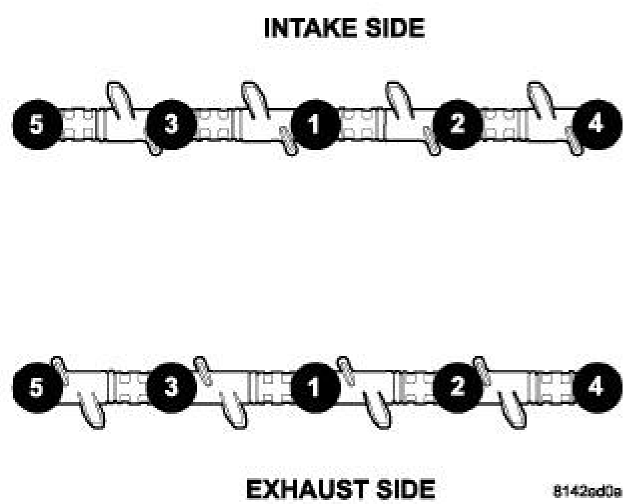


Fig. 55: Rocker Shaft Torque Sequence

CAUTION: The rocker shaft assemblies are not interchangeable between intake and exhaust. The intake rocker arms are marked with the letter "I".

4. Verify the rocker arms are installed in the correct location.

NOTE: Repeat torque sequence several times to ensure rocker shaft assembly is firmly seated.

5. Using the sequence shown in illustration, tighten the rocker shaft bolts as follows:
   - Snug to 10 N.m (7 ft. lbs.)
   - Torque to 23 N.m (17 ft. lbs.)
   - Individually loosen by 1/2 turn and retorque to 23 N.m (17 ft. lbs.)
   - Finally, Rotate 30 degrees

7. Install the cylinder head cover. Refer to **COVER(S), CYLINDER HEAD, INSTALLATION**.

SEAL(S), VALVE GUIDE

DESCRIPTION

DESCRIPTION

The valve guide seals are made of black rubber and incorporate an integral steel garter spring. The integral garter spring maintains consistent lubrication control to the valve stems. The intake and exhaust stem seals are common with each other.

SPRING(S), VALVE

REMOVAL

REMOVAL

1. Disconnect and isolate the negative battery cable.
2. Remove the air cleaner body. Refer to **BODY, AIR CLEANER, INSTALLATION**.
3. Remove the cylinder head covers. Refer to **COVER(S), CYLINDER HEAD, REMOVAL**.

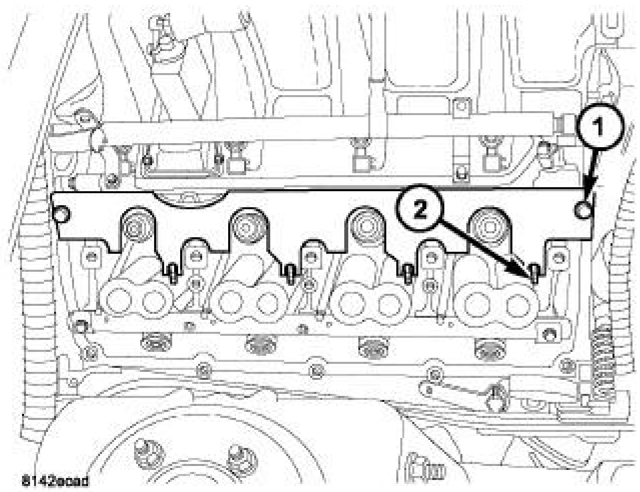

Fig. 58: Pushrod Retaining Plate

CAUTION: **The piston must be at TDC, and both valves closed on the cylinder to be serviced.**

NOTE: **The intake push rods can fall into the engine and become lodged in the oil pan, if removing intake rocker arm shaft, install the push rod retainer (special tool #9070, Retainer, Push Rod) (1) to retain the intake push rods (2).**

4. Install the push rod retainer (special tool #9070, Retainer, Push Rod) (1) onto the cylinder head.
5. Clip the push rods (2) into the push rod retainer (1).

NOTE:	**A fulcrum assembly (1) must be rotated to the appropriate setting as marked on the tool for proper valve spring alignment.**
NOTE:	**All valve springs and seals are removed in the same manner.**
NOTE:	**Tap the top of the valve spring retainer to loosen the spring retainer locks.**

9. Install the (special tool #9065C, Compressor, Valve Spring) (1) and remove the intake valve retainer locks.
10. Release the valve spring compressor and remove the valve springs.

11. Install the (special tool #9065C, Compressor, Valve Spring) (2) and the (special tool #9065-3, Adapter, Valve Spring Compressor) (1) and remove the exhaust valve retainer locks.
12. Release the valve spring compressor and remove the valve spring.

NOTE: The valve springs are interchangeable between intake and exhaust.

13. Remove and discard the valve guide seal.

INSTALLATION

INSTALLATION

NOTE: All valve springs and seals are installed in the same manner.

1. Install a new valve guide seal.

NOTE: The intake spring retainer has a longer free length compared to the exhaust spring retainer.

2. Install the valve spring.
3. Install the valve spring retainer.

5. Remove the (special tool #9065C, Compressor, Valve Spring) (2) and the (special tool #9065-3, Adapter, Valve Spring Compressor).
6. Release the air charge (1) in the cylinder.

CAUTION: Verify that the pushrods are fully seated into the lifters and the rocker arms. Recheck after rocker arm shaft has been torqued to specification.

7. Install the rocker arm shaft and push rods. Refer to **ROCKER ARM, VALVE, INSTALLATION**.

9. Remove the (special tool #9070, Retainer, Push Rod) (1).
10. Install the cylinder head cover. Refer to **COVER(S), CYLINDER HEAD, INSTALLATION**.
11. Install the air cleaner body. Refer to **BODY, AIR CLEANER, INSTALLATION**.
12. Connect the negative battery cable.

VALVES, INTAKE AND EXHAUST

DESCRIPTION

VALVES

Both the intake and exhaust valves are made of steel with full chrome plate on valve stems. The intake valve is 54.3 mm (2.14 in.) diameter and the exhaust valve is 42.0 mm (1.65 in.) diameter. All valves use three bead lock keepers and retainers to retain the springs and promote valve rotation.

VALVE GUIDES

The valve guides are made of powdered metal and are pressed into the cylinder head. The guides are not replaceable or serviceable, and valve guide reaming is not recommended. If the guides are worn beyond acceptable limits, replace the cylinder heads.

STANDARD PROCEDURE

STANDARD PROCEDURE - REFACING

NOTE: Valve seats that are worn or burned can be reworked, provided that the correct angle and seat width are maintained. Otherwise the cylinder head must be replaced.

NOTE: When refacing valves and valve seats, it is important that the correct size valve guide pilot be used for reseating stones. A true and complete surface must be obtained.

1. Measure the concentricity of the valve seat using a dial indicator. Total runout should not exceed 0.051 mm (0.002 inch.) total indicator reading.
2. Inspect the valve seat with Prussian blue to determine where the valve contacts the seat. To do this, coat the valve seat with Prussian blue then set the valve in place. Rotate the valve using light pressure. If the blue is transferred to the center of the valve face, contact is satisfactory. If the blue is transferred to the top edge of the valve face, lower the valve seat with a 15 degree stone. If the blue is transferred to the bottom edge of the valve face, raise the valve seat with a 65 degree stone.
3. Refer to the VALVE SEAT, VALVE FACE AND SPRING HEIGHT CHART for the proper valve seat width, valve seat angle, valve face angle and valve spring height.

VALVE SEAT, VALVE FACE AND SPRING HEIGHT CHART

DESCRIPTION	SPECIFICATION	
SEAT WIDTH		
INTAKE	0.94 - 1.04 mm	0.037 - 0.041 in.
EXHAUST	1.16 - 1.26 mm	0.046 - 0.050 in.
SEAT ANGLE		
(INT. AND EXT.)	44.5Â° - 45Â°	
FACE ANGLE		
INTAKE	45.5Â° - 46Â°	
EXHAUST	45Â° - 45.5Â°	
SPRING HEIGHT		
INTAKE	52.1 mm	2.051 in.
EXHAUST	51.2 mm	2.016 in.

4. The valve seat must maintain an angle of 44.5Â° - 45.0Â°.
5. The valve face must maintain an angle of 45.5Â° - 46.0Â° for the Intake and 45.0Â° - 45.5Â° for the exhaust.

REMOVAL

REMOVAL

1. Disconnect and isolate the negative battery cable.
2. Remove the cylinder head. Refer to **CYLINDER HEAD, REMOVAL**.
3. Compress the valve springs using the valve spring compressor (special tool #C-3422-D, Compressor, Valve Spring) and adapter (special tool #8464, Adapter, Valve Spring).

4. Remove the valve spring retainer locks, valve spring retainers, valve stem seals and valve springs.
5. Before removing the valves, remove any burrs from the valve spring retainer lock grooves in the valve stems to prevent damage to the valve guides. Identify the valves to ensure installation in their original location.
6. Remove the valves.

INSTALLATION

INSTALLATION

1. Clean the valves thoroughly. Discard burned, warped, and cracked valves.
2. Remove carbon and varnish deposits from inside the valve guides with a reliable guide cleaner.
3. Measure the valve stems for wear. If wear exceeds 0.051 mm (0.002 inch), replace the valve.
4. Coat the valve stems with clean engine oil and insert them into the cylinder head.
5. If the valves or seats have been reground, check valve stem height. If the valve is too long, replace the cylinder head.
6. Install new seals on all valve guides. Install the valve springs and valve spring retainers.

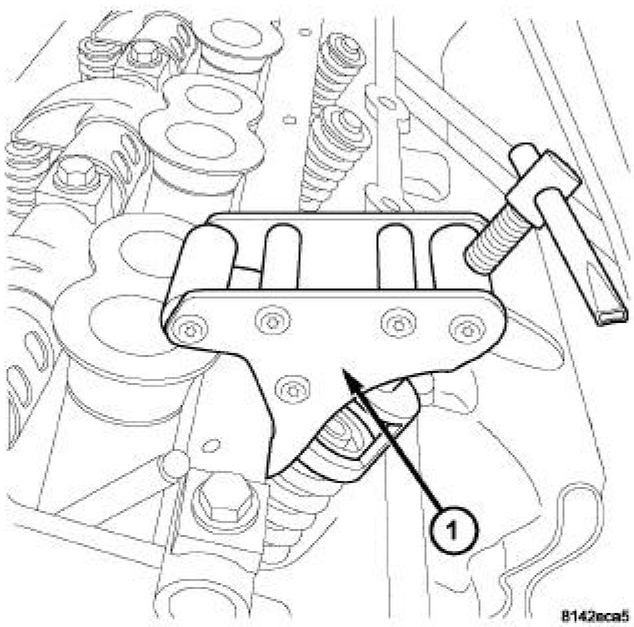

Fig. 67: Exhaust Valve Spring Removal/Installation
Courtesy of CHRYSLER GROUP, LLC

7. Compress the valve springs with the Valve Spring Compressor (special tool #C-3422-D, Compressor, Valve Spring) (1) and Adapter (special tool #8464, Adapter, Valve Spring), install the valve spring retainer locks and release the tool. If the valves and/or seats have been ground, measure the installed height of the springs. Make sure the measurement is taken from the bottom of spring seat in the cylinder head to the bottom surface of valve spring retainer.
8. Install the cylinder head. Refer to **CYLINDER HEAD, INSTALLATION**.
9. Connect the negative battery cable.

ENGINE BLOCK

CLEANING

CLEANING

Thoroughly clean the oil pan and engine block gasket surfaces.

Use compressed air to clean the following:

- Gallery at the oil filter adaptor hole.
- Front and rear oil gallery holes.
- Feed holes for the crankshaft main bearings.

Once the block has been completely cleaned, apply Loctite PST pipe sealant with Teflon 592 to the threads of the front and rear oil gallery plugs. Tighten the 1/4 inch NPT plugs, 3/8 inch NPT plugs and the coolant drain plugs to the proper specification. Refer to **TORQUE SPECIFICATIONS**.

INSPECTION

INSPECTION

ENGINE BLOCK

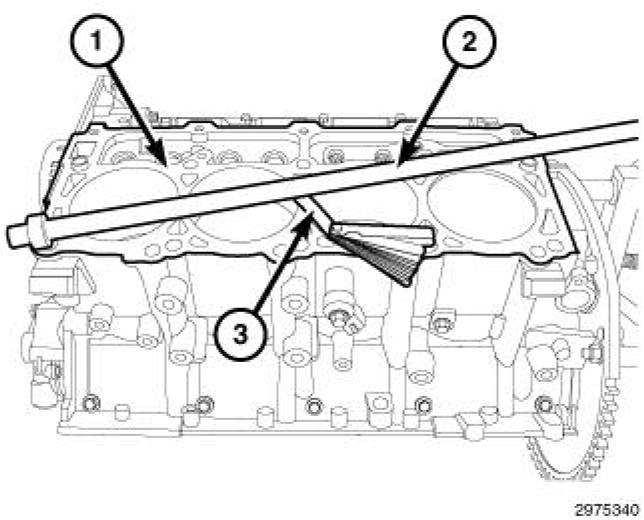

Fig. 68: Checking Engine Block Deck Surface With Precision Straightedge & Feeler Gauge
Courtesy of CHRYSLER GROUP, LLC

1. Clean the engine block thoroughly and check all core hole plugs for evidence of leaking and repair if necessary.
2. Examine the engine block and cylinder bores for cracks or fractures.

NOTE: **Check the engine block deck surface with a precision straightedge and feeler gauge. The surface irregularities should not exceed 0.09 mm (0.0035 in.). Check the deck surface from one end to the other with the precision straightedge positioned across corners and parallel to the block centerline**

up and down the deck.

3. Check the engine block deck (1) surfaces for flatness using a precision straightedge (2) and feeler gauge (3).

CYLINDER BORE

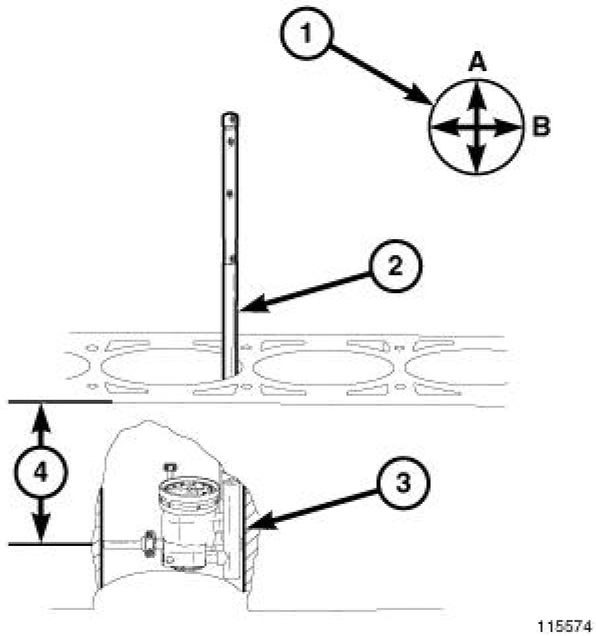

Fig. 69: Measuring Cylinder Bore Diameter
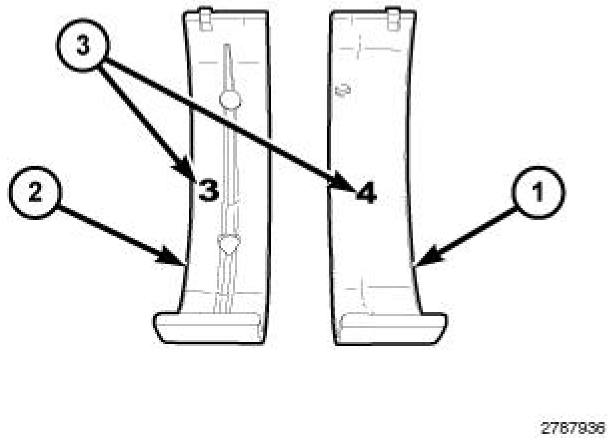
Courtesy of CHRYSLER GROUP, LLC

1. Use Cylinder Indicator (special tool #C-119, Cylinder Indicator) (2) to correctly measure the inside diameter of the cylinder bore (3). A cylinder bore gauge capable of reading in 0.003 mm (0.0001 in.) increments is required. If a bore gauge is not available, do not use an inside micrometer.
2. Measure the inside diameter of the cylinder bore at three levels below the top of the bore (4). Start at the top of the bore, perpendicular (across or at 90Ā°) to the axis of the crankshaft at point A (1).
3. Repeat the measurement near the middle of the bore then repeat the measurement near the bottom of the bore.
4. Determine the taper by subtracting the smaller diameter from the larger diameter.
5. Rotate the measuring device 90Ā° to point B (1) and repeat the three measurements. Verify that the maximum taper is within specifications.
6. Determine out-of-roundness by comparing the difference between each measurement.
7. If the cylinder bore taper does not exceed 0.0127 mm (0.0005 inch) and out-of-roundness does not exceed 0.008 mm (0.0003 inch) then the cylinder bore can be honed. If the cylinder bore taper or out- of-round condition exceeds the maximum limits, replace the engine block.

NOTE: **A slight amount of taper always exists in the cylinder bore after the engine has been in use for a period of time.**

MAIN BEARINGS



[Fig. 70: Main Bearing Inserts]
Courtesy of CHRYSLER GROUP, LLC

1. Wipe the main bearing inserts (1, 2) clean.
2. Inspect the inserts for abnormal wear patterns, scoring, grooving, fatigue, pitting and for metal or other foreign material imbedded in the lining.
3. Inspect the back of the inserts for fractures, scrapes or irregular wear patterns.
4. Inspect the insert locking tabs for damage.
5. Inspect the crankshaft thrust washers for scoring, scratches, bluing, discoloration or signs of wear.
6. Replace any bearing that shows abnormal wear.
7. Inspect the main bearing bores for signs of scoring, nicks and burrs.
8. If the engine block main bearing bores show damage, replace the engine block.

BEARING(S), CRANKSHAFT, MAIN

STANDARD PROCEDURE

STANDARD PROCEDURE - CRANKSHAFT MAIN BEARING - FITTING

MAIN BEARING JOURNAL DIAMETER (CRANKSHAFT REMOVED)

CAUTION: If the engine encounters a catastrophic failure, the engine oil cooler and lines must be replaced or damage to the new engine and/or components could result.

Crankshaft removed from the cylinder block.

Clean the oil off the main bearing journal.

Determine the maximum diameter of the journal with a micrometer. Measure at two locations 90Ā° apart at each end of the journal.

The maximum allowable taper is 0.003 mm (0.00012 inch). The maximum out-of-round is 0.005 mm (0.0002 inch). Compare the measured diameter with the journal diameter specification (Main Bearing Fitting Chart). Select inserts required to obtain the specified bearing-to-journal clearance.

CRANKSHAFT MAIN BEARING SELECTION

The main bearings are "select fit" to achieve proper oil clearances. For main bearing selection, the crankshaft counterweight has grade identification marks stamped into it. These marks are read from left to right, corresponding with journal number 1, 2, 3, 4 and 5.

NOTE: **Service main bearings are coded. These codes identify what size (color) the bearing is.**

MAIN BEARING SELECTION CHART

GRADE	COLOR	mm	In	FOR USE WITH JOURNAL SIZE
-	**LOWER AND UPPER**	-	-	64.9780-64.9859 mm
A	**ORANGE**	0.008 mm U/S	(0.0004 in.) U/S	(2.442-2.447 in.)
-	**LOWER AND UPPER**	-	-	664.9860-64.9940 mm
B	**BLACK**	NOMINAL	NOMINAL	(2.438-2.443 in.)
-	**LOWER AND UPPER**	-	-	64.9941-65.0020 mm
C	**GREEN**	0.008 mm O/S	(0.0004 in.) O/S	(2.434-2.439 in.)

INSPECTION

INSPECTION

CAUTION: **If the engine encounters a catastrophic failure, the engine oil cooler and lines must be replaced or damage to the new engine and/or components could result.**

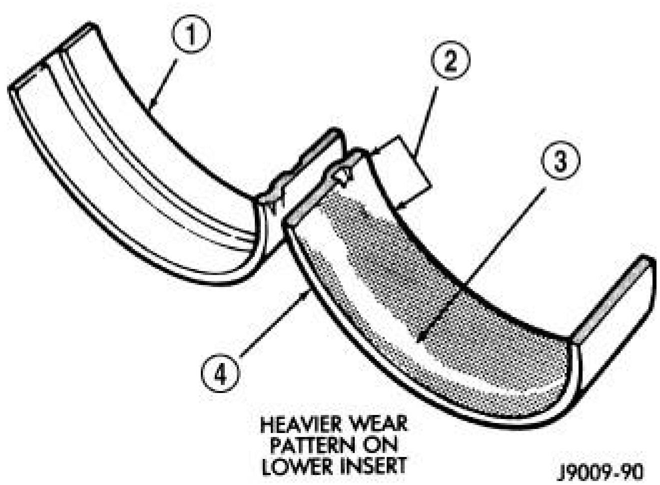


Fig. 71: Main Bearing Wear Patterns
Courtesy of CHRYSLER GROUP, LLC

Wipe the inserts clean and inspect for abnormal wear patterns and for metal or other foreign material imbedded in the lining. Normal main bearing insert wear patterns are illustrated.

NOTE: If any of the crankshaft journals are scored, the crankshaft must be repaired or replaced.

Inspect the back of the inserts for fractures, scoring or irregular wear patterns.

Inspect the upper insert locking tabs for damage.

Replace all damaged or worn bearing inserts.

CAMSHAFT, ENGINE

REMOVAL

CAMSHAFT CORE HOLE PLUG

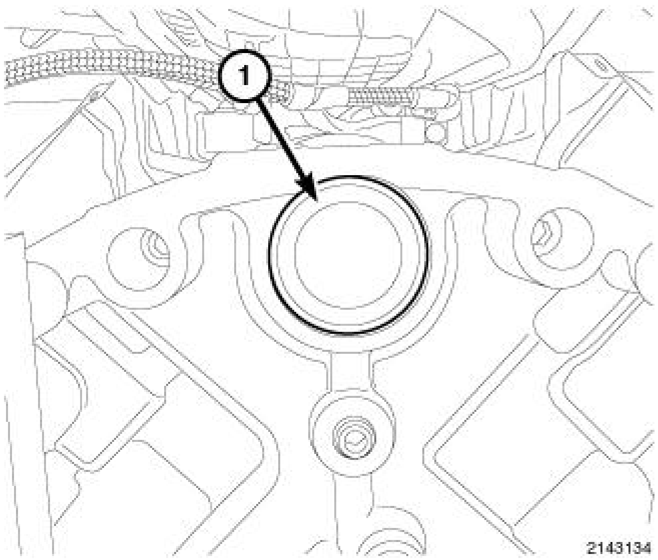

Fig. 72: Camshaft Core Hole Plug
Courtesy of CHRYSLER GROUP, LLC

1. Perform the fuel system pressure release procedure. Refer to **FUEL DELIVERY, GAS, STANDARD PROCEDURE** .
2. Remove the engine from the vehicle. Refer to **REMOVAL**.
3. On automatic transmission models, remove the flexplate. Refer to **FLEXPLATE, REMOVAL**.
4. On manual transmission models, remove the flywheel. Refer to **FLYWHEEL, REMOVAL** .

CAUTION: Do not damage the rear surface of the camshaft or the core plug sealing surface, when removing the core plug.

5. Using a suitable sharp punch, punch a small hole in the camshaft core hole plug (1).
6. Insert a short sheet metal screw into the small hole in the camshaft core hole plug.
7. Using a suitable slide hammer puller, remove the rear camshaft core hole plug.

CAMSHAFT

1. Remove both cylinder heads. Refer to **CYLINDER HEAD, REMOVAL**.

CAUTION: **Whenever the camshaft is replaced, all lifters must be replaced. If the lifter and retainer assemblies are to be reused, identify the lifters to ensure installation in their original location or engine damage could result.**

CAUTION: **The lifter and retainer assembly must be installed as a unit.**

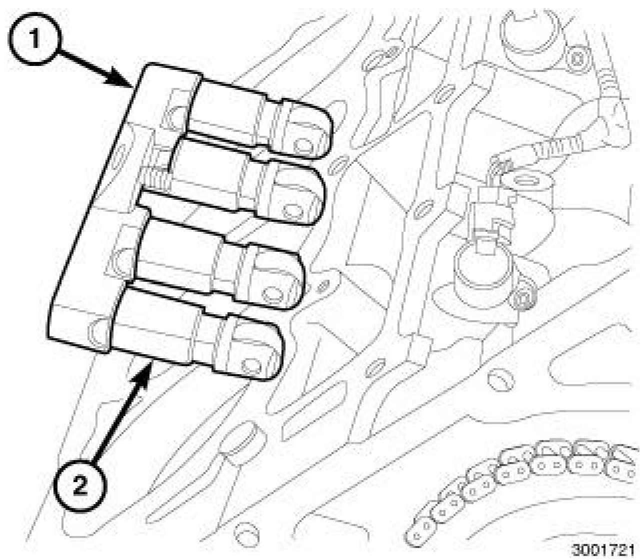

Fig. 73: Identifying Lifters & Retainers

7. Install a long bolt (2) into the front of the camshaft to aid in removal.
8. Remove the camshaft using care not to damage the camshaft bearings with the camshaft lobes (1).

INSPECTION

INSPECTION

NOTE: **The cam bearings are not serviceable. Do not attempt to replace cam bearings for any reason.**

INSTALLATION

CAMSHAFT CORE HOLE PLUG

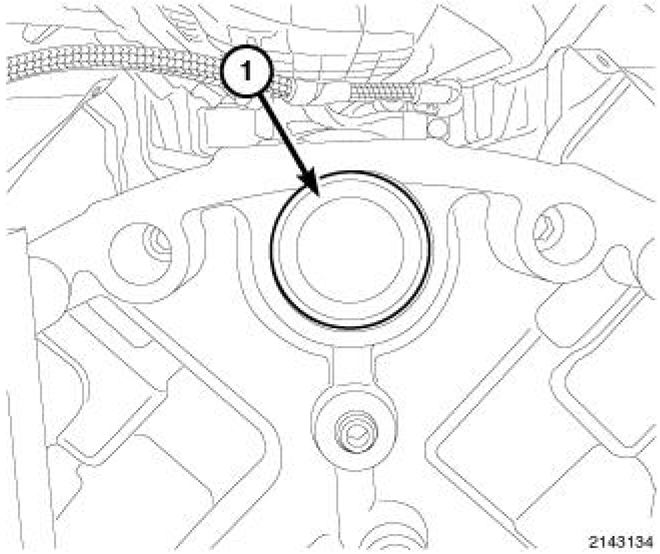

Fig. 76: Camshaft Core Hole Plug
Courtesy of CHRYSLER GROUP, LLC

1. Clean the core hole in the cylinder block.

NOTE: **Do not apply adhesive to the new camshaft core hole plug. A new plug has adhesive pre-applied.**

2. Install a new camshaft core hole plug (1) located at the rear of cylinder block, using a suitable flat faced tool. The plug must be fully seated on the cylinder block shoulder.
3. On manual transmission models, install the flywheel. Refer to **FLYWHEEL, INSTALLATION** .
4. On automatic transmission models, install the flexplate. Refer to **FLEXPLATE, INSTALLATION**.
5. Install the engine. Refer to **INSTALLATION**.

CAMSHAFT

CAUTION: **Use care when installing the camshaft into the engine block, do not damage the camshaft bearings with the camshaft lobes.**

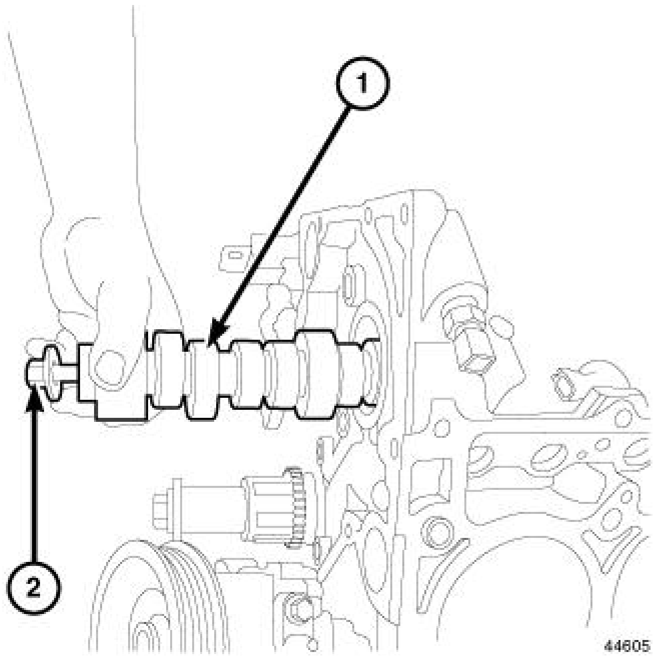

Fig. 77: Removing/Installing Camshaft
Courtesy of CHRYSLER GROUP, LLC

1. Lubricate the camshaft lobes (1) and the camshaft bearing journals with clean engine oil.
2. Install a long bolt (2) into the front of the camshaft to aid in the installation, carefully install the camshaft into the engine block.

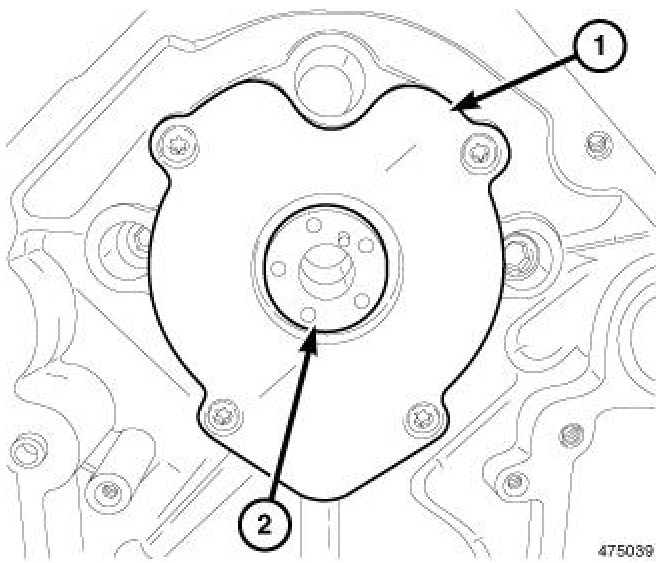

Fig. 78: Camshaft Thrust Plate
Courtesy of CHRYSLER GROUP, LLC

3. Install the camshaft thrust plate (1) and tighten retaining bolts to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
4. Using a suitable dial indicator, measure the camshaft end play. Refer to **ENGINE SPECIFICATIONS**. If not within specification, install a new thrust plate.
5. Install the timing chain and camshaft phaser. Refer to **CHAIN AND SPROCKETS, TIMING, INSTALLATION**.

6. Install the A/C condenser. Refer to **CONDENSER, A/C, INSTALLATION** .
7. Install the radiator. Refer to **RADIATOR, ENGINE COOLING, INSTALLATION** .

CAUTION: **Whenever the camshaft is replaced, all lifters must be replaced. If the lifter and retainer assemblies are to be reused, identify the lifters to ensure installation in their original location or engine damage could result.**

CAUTION: **The lifter and retainer assembly must be installed as a unit.**

8. Install the lifters (2) and retainer (1) as an assembly into their original location. Refer to **LIFTER(S), HYDRAULIC, ROLLER, INSTALLATION**.
9. Install both cylinder heads. Refer to **CYLINDER HEAD, INSTALLATION**.

NOTE: **The Cam/Crank Variation Relearn procedure must be performed using the scan tool anytime there has been a repair/replacement made to a powertrain system. For example: flywheel, valvetrain, camshaft and/or crankshaft sensors or components.**

CRANKSHAFT

REMOVAL

REMOVAL

CAUTION: **If the engine encounters a catastrophic failure, the engine oil cooler and lines must be replaced or damage to the new engine and/or components could result.**

1. Remove the engine. Refer to **REMOVAL**.
2. Secure the engine onto a suitable engine stand.
3. Remove the crankshaft rear oil seal retainer. Refer to **RETAINER, CRANKSHAFT REAR OIL SEAL, REMOVAL**.

4. Remove the oil pan and the oil pump pickup tube. Refer to **PAN, OIL, REMOVAL**.
5. Remove the timing chain, camshaft phaser and crankshaft sprocket. Refer to **CHAIN AND SPROCKETS, TIMING, REMOVAL**.

CAUTION: Do not use a number stamp or a punch to mark connecting rods or caps, as damage to connecting rods could occur.

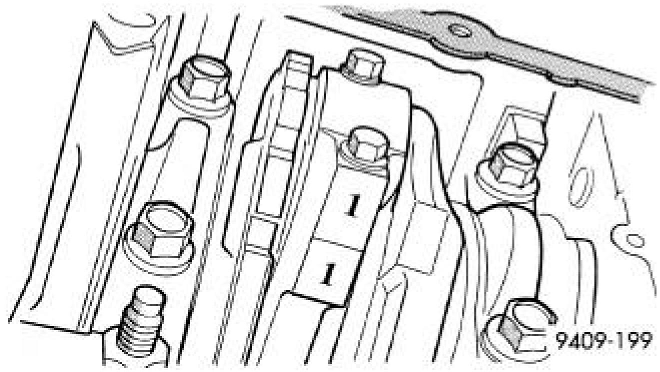

Fig. 80: Identifying Mark On Connecting Rod And Bearing Cap

NOTE: Connecting rods and bearing caps are not interchangeable and should be marked before removal to ensure correct reassembly.

6. Mark the connecting rod and bearing cap location using a permanent ink marker or scribe tool.
7. Remove the rod bearing caps and bearings.

CAUTION: Do not use a number stamp or a punch to mark main bearing caps as damage to bearing caps and/or bearings could occur.

NOTE: Main bearing caps are not interchangeable and should be marked before removal to ensure correct reassembly.

8. Mark the main bearing caps using a permanent ink marker or scribe tool.

NOTE: **The main bearing cap cross-bolts are torqued after the final torque of the main cap bolts.**

12. Install the cross-bolts finger tight.
13. Using the sequence shown in illustration, tighten the cross-bolts to 34 N.m (25 ft. lbs.).
14. Again, using the sequence shown in illustration, repeat the cross-bolt tightening procedure using the same torque.
15. Measure the crankshaft end play. Refer to **STANDARD PROCEDURE**.

CAUTION: **The connecting rod bolts must not be reused. Always replace the connecting rod bolts whenever they are loosened or removed.**

20. If required, measure the connecting rod side clearance (1, 2). Refer to ENGINE SPECIFICATIONS.
21. Install the timing chain, camshaft phaser and crankshaft sprocket. Refer to CHAIN AND SPROCKETS, TIMING, INSTALLATION.
22. Install the crankshaft rear oil seal retainer. Refer to RETAINER, CRANKSHAFT REAR OIL SEAL, INSTALLATION.
23. Install the oil pump pickup tube and oil pan. Refer to PAN, OIL, INSTALLATION.
24. Install the engine. Refer to INSTALLATION.
25. Start the engine and check for leaks.

NOTE: **The Cam/Crank Variation Relearn procedure must be performed using the scan tool anytime there has been a repair/replacement made to a powertrain system. For example: flywheel, valvetrain, camshaft and/or crankshaft sensors or components.**

DAMPER, VIBRATION

DESCRIPTION

DESCRIPTION

[Fig. 92: Crankshaft Damper](#)
Courtesy of CHRYSLER GROUP, LLC

The crankshaft damper is used to control the resonance that is produced by the engine. The Noise, Vibration, and Harshness (NVH) created from the crankshaft can be controlled by dissipating the torque energy through the damper.

The crankshaft damper is held to the crankshaft by means of a harden steel bolt. The damper is pressed onto a specific machined surface of the crankshaft.

REMOVAL

REMOVAL

1. Disconnect and isolate the negative battery cable.
2. Remove the cooling fan assembly. Refer to **FAN, COOLING, REMOVAL** .

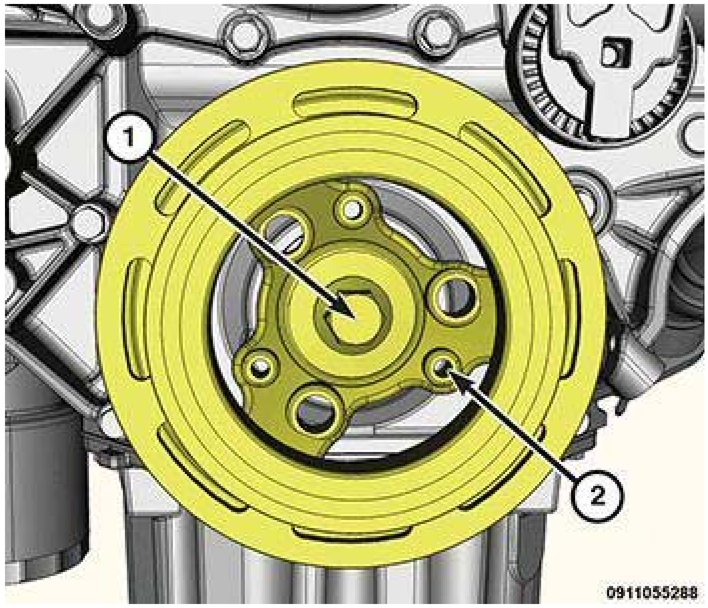

Fig. 93: Crankshaft Damper & Bolt

NOTE: **When installing the puller tool, ensure the bolts are fully threaded through the entire crankshaft damper (2).**

3. Remove the vibration damper bolt (1) and discard.
4. Install the crankshaft damper puller, making sure the bolts are fully threaded through the entire crankshaft damper.
5. Remove the crankshaft damper.

INSTALLATION

INSTALLATION

1. Using a commercially available damper installer, install the 16 mm threaded rod into the crankshaft.
2. Tighten the threaded rod until it is seated to the face of the crankshaft.

3. Position the damper (2) on the crankshaft.
4. Install the press washer, bearing, washer, and the press nut onto the threaded rod.
5. Using Damper Installer and a deep well socket, press the damper onto the crankshaft until seated.
6. Install a New vibration damper bolt (1).
7. Position the (special tool #10386, Holder, Vibration Damper), onto the vibration damper pulley.
8. Tighten the bolt to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
9. Install the cooling fan. Refer to **FAN, COOLING, INSTALLATION** .
10. Connect the negative battery cable.

LIFTER(S), HYDRAULIC, ROLLER

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - HYDRAULIC ROLLER LIFTERS

Before disassembling any part of the engine to correct lifter noise, check the oil pressure. If the vehicle has no oil pressure gauge, install a reliable gauge at the pressure sending-unit. The pressure should be between 207-552 kPa (30-70 psi) at 3, 000 RPM.

Check the oil level after the engine reaches normal operating temperature. Allow 5 minutes to stabilize oil level, check dipstick. The oil level in the pan should never be above the FULL mark or below the ADD OIL mark on the dipstick. Either of these two conditions could be responsible for noisy lifters.

OIL LEVEL

HIGH

If oil level is above the FULL mark, it is possible for the connecting rods to dip into the oil. With the engine running, this condition could create foam in the oil pan. Foam in oil pan would be fed to the hydraulic lifters by the oil pump causing them to lose length and allow valves to seat noisily.

LOW

Low oil level may allow oil pump to take in air. When air is fed to the lifters, they lose length, which allows valves to seat noisily. Any leaks on intake side of oil pump through which air can be drawn will create the same lifter action. Check the lubrication system from the intake strainer to the pump cover, including the relief valve retainer cap. When lifter noise is due to aeration, it may be intermittent or constant, and usually more than one lifter will be noisy. When oil level and leaks have been corrected, operate the engine at fast idle. Run engine for a sufficient time to allow all of the air inside the lifters to be bled out.

LIFTER NOISE DIAGNOSIS

1. To determine source of lifter noise, crank the engine with cylinder head covers removed.
2. Feel each valve spring or rocker arm to detect noisy lifter. The noisy lifter will cause the affected spring and/or rocker arm to vibrate or feel rough in operation.

NOTE: **Worn valve guides or cocked springs are sometimes mistaken for noisy lifters. If such is the case, noise may be dampened by applying side thrust on the valve spring. If noise is not noticeably reduced, it can be assumed the noise is in the lifter. Inspect the rocker arm push rod sockets and push rod ends for wear.**

3. Valve lifter noise ranges from light noise to a heavy click. A light noise is usually caused by excessive leak-down around the unit plunger or by the plunger partially sticking in the lifter body cylinder. The lifter should be replaced. A heavy click is caused by a lifter check valve not seating or by foreign particles wedged between the plunger and the lifter body. This will cause the plunger to stick in the down position. This heavy click will be accompanied by excessive clearance between the valve stem and rocker arm as the valve closes. In either case, lifter assembly should be removed for inspection and cleaning.
4. The valve train generates a noise very much like a light lifter noise during normal operation. Care must be taken to ensure that lifters are making the noise. If more than one lifter seems to be noisy, it's probably not the lifters.

REMOVAL

REMOVAL

1. Disconnect and isolate the negative battery cable.
2. Remove the cylinder head. Refer to **CYLINDER HEAD, REMOVAL**.

CAUTION: If the lifter and retainer assembly are to be reused, identify the lifters to ensure installation in their original location or engine damage could result.

CAUTION: The lifter and retainer assembly must be installed as a unit.

3. Remove the lifters (2) and retainer (1) as an assembly.
4. Check the camshaft lobes for abnormal wear.

INSTALLATION

CAUTION: If the lifter and retainer assembly are to be reused, identify the lifters to ensure installation in their original location or engine damage could result.

CAUTION: The lifter and retainer must be installed as an assembly.

2. Install the lifters (2) and retainer (1) as an assembly into their original location.
3. Tighten the lifter retainer bolt (1) to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
4. Install the cylinder head. Refer to **CYLINDER HEAD, INSTALLATION**.
5. Connect the negative battery cable.

CAUTION: To prevent damage to valve assemblies, do not run the engine above fast idle until all hydraulic lifters have filled with oil and have become quiet.

RETAINER, CRANKSHAFT REAR OIL SEAL

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - REAR SEAL AREA LEAKS

The crankshaft rear oil seal is integral to the crankshaft rear oil seal retainer and is serviced as an assembly.

Since it is sometimes difficult to determine the source of an oil leak in the rear seal area of the engine, a more involved inspection is necessary. The following steps should be followed to help pinpoint the source of the leak.

If the leakage occurs at the crankshaft rear oil seal area:

1. Raise and support the vehicle.
2. Remove the transmission inspection/torque converter access cover.
3. Inspect the rear of the cylinder block for evidence of oil leakage and note the following:
   - Circular spray pattern generally indicates seal leakage or crankshaft damage.

- Where leakage tends to run straight down, possible causes are a porous block, camshaft bore cup plugs, oil gallery pipe plugs, oil filter runoff and main bearing cap to cylinder block mating surfaces. See appropriate Engine component for proper repair procedures of these items.

4. If no leaks are detected, pressurize the crankcase as outlined in the **AIR LEAK DETECTION TEST METHOD**.

   CAUTION: Do not exceed 20.6 kPa (3 psi).

5. If the leak is not detected, very slowly turn the crankshaft and watch for leakage. If a leak is detected between the crankshaft and seal while slowly turning the crankshaft, it is possible the crankshaft seal surface is damaged. The seal area on the crankshaft could have minor nicks or scratches that can be polished out using an emery cloth.

   CAUTION: Use extreme caution when crankshaft polishing is necessary to remove minor nicks or scratches. The crankshaft seal flange is specially machined to complement the function of the rear oil seal.

6. For bubbles that remain steady with shaft rotation, no further inspection can be done. Refer to **RETAINER, CRANKSHAFT REAR OIL SEAL, REMOVAL**.

REMOVAL

REMOVAL

NOTE: The crankshaft rear oil seal is integral to the crankshaft rear oil seal retainer and must be replaced as an assembly.

NOTE: The crankshaft rear oil seal retainer can not be reused after removal.

NOTE: This procedure can be performed in vehicle.

1. Disconnect the negative battery cable.
2. Remove the flexplate or flywheel. Refer to **FLEXPLATE, REMOVAL**.
3. Remove the oil pan. Refer to **PAN, OIL, REMOVAL**.

4. Using the sequence shown in illustration, remove the rear oil seal retainer mounting bolts.
5. Remove and discard the rear oil seal retainer.

INSTALLATION

INSTALLATION

NOTE: **The crankshaft rear oil seal is integral to the crankshaft rear oil seal retainer and must be replaced as an assembly.**

NOTE: **The crankshaft rear oil seal retainer can not be reused after removal.**

1. Thoroughly clean all gasket residue from the engine block.
2. Position the gasket onto the new crankshaft rear oil seal retainer.
3. Position the crankshaft rear oil seal retainer onto the engine block.

4. Using the sequence shown in illustration, install the crankshaft rear oil seal retainer mounting bolts and tighten to the proper specification. Refer to **ENGINE SPECIFICATIONS**.
5. Install the oil pan. Refer to **PAN, OIL, INSTALLATION**.
6. Install the flexplate or flywheel. Refer to **FLEXPLATE, INSTALLATION**.
7. Install a NEW oil filter and fill the crankcase with the specified type and amount of engine oil. Refer to **STANDARD PROCEDURE**.
8. Connect the negative battery cable.
9. Start the engine and check for leaks.

RING(S), PISTON

STANDARD PROCEDURE

STANDARD PROCEDURE

PISTON RING FITTING

CAUTION: Before reinstalling used piston rings or installing new piston rings, the piston ring clearances must be checked or engine damage may result.

1. Wipe the cylinder bore clean.
2. Insert the piston ring into the cylinder bore.

NOTE: The piston ring gap measurement must be made with the piston ring positioned at least 12 mm (0.50 inch) from bottom of cylinder bore.

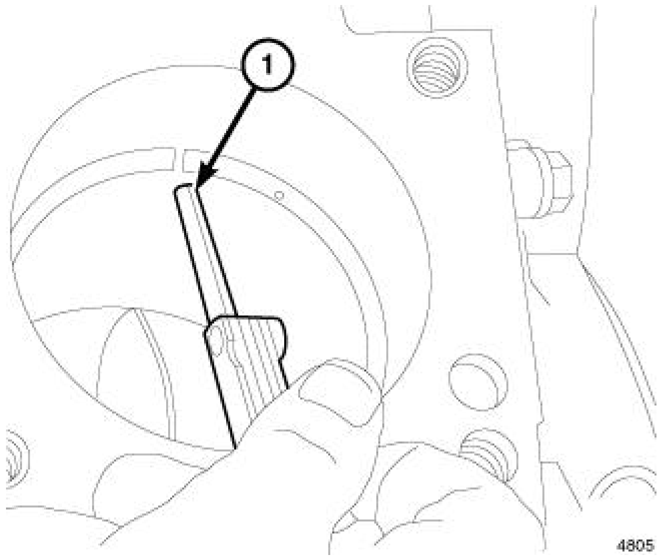

Fig. 102: Using Feeler Gauge To Check Ring End Gap
Courtesy of CHRYSLER GROUP, LLC

3. Using a piston, make sure that the piston ring is squared in the cylinder bore. Slide the piston ring downward into the cylinder.
4. Using a feeler gauge (1), check the piston ring end gap, replace any rings not within specification.

PISTON RING SIDE CLEARANCE

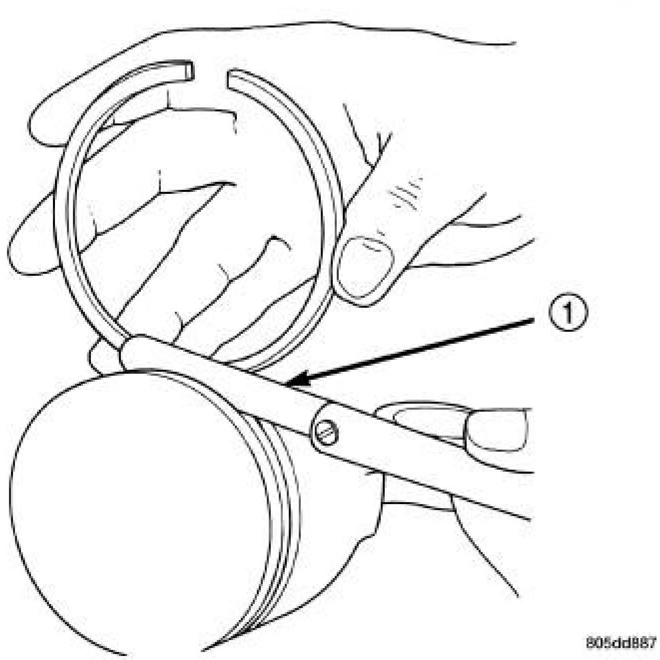

Fig. 103: Checking Piston Ring Grooves Clearances
Courtesy of CHRYSLER GROUP, LLC

NOTE: Make sure the piston ring grooves are clean and free of nicks and burrs.

1. Measure the piston ring side clearance with a feeler gauge (1) as shown in illustration. Make sure the

feeler gauge fits snugly between the piston ring land and the piston ring, replace any ring not within specification.

NOTE: **Make sure the marks on the compression rings face upward.**

2. Rotate the ring around the piston. The ring must rotate in the groove with out binding.

PISTON RING INSTALLATION

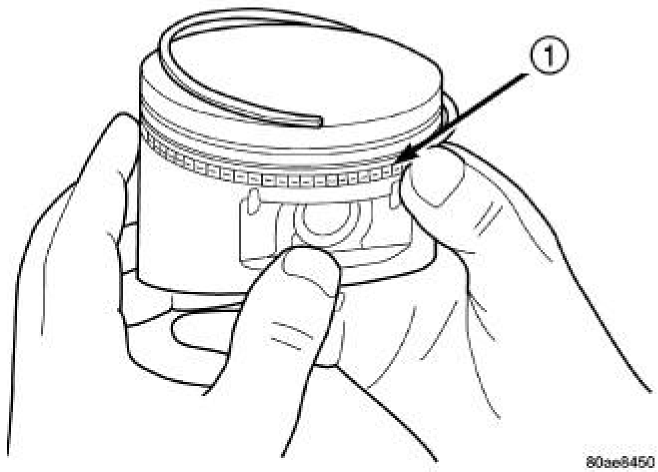

Fig. 104: Installing Piston Ring Side Rail
Courtesy of CHRYSLER GROUP, LLC

1. Install the oil ring expander.
2. Install the lower side rail by placing one end between the piston ring groove and the expander ring (1). Hold the lower side rail end firmly and press down the portion to be installed until the side rail is in position. Repeat this step for the upper side rail.

5. Install the oil ring expander gap at the (5) position.
6. Install the oil ring lower side rail gap at the (4) position.
7. Install the oil ring upper side rail gap at the (1) position.
8. Install the second compression ring gap at the (5) position.
9. Install the top compression ring gap at the (2) position.

ROD, PISTON AND CONNECTING

DESCRIPTION

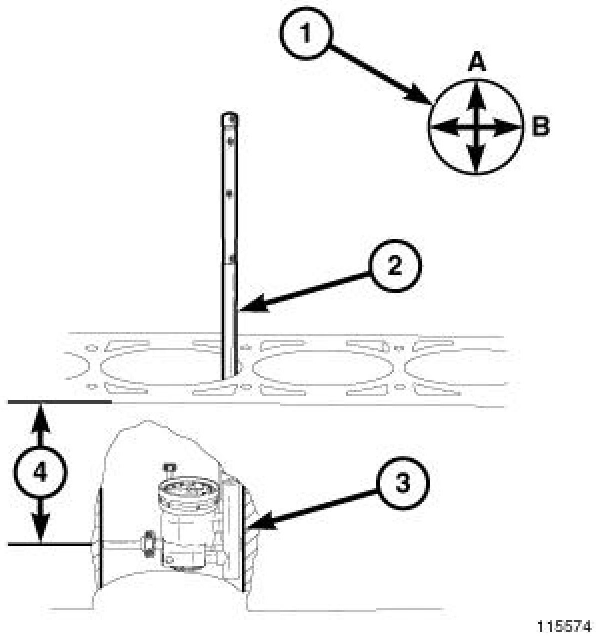
DESCRIPTION

CAUTION: Do not use a metal stamp to mark connecting rods as damage may result, instead use ink or a scratch awl.

The pistons are made of a high-strength forged aluminum alloy. Piston skirts are coated with a solid graphite lubricant to reduce friction and provide scuff resistance. The piston top ring groove and land is anodized. The connecting rods are made of forged powdered metal with a "fractured cap" design. A floating piston pin is used to attach the piston and connecting rod.

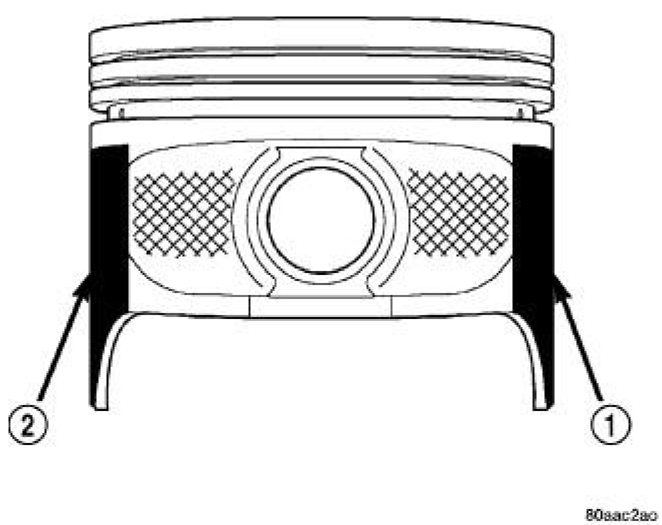
STANDARD PROCEDURE

STANDARD PROCEDURE - PISTON FITTING



[Fig. 107: Measuring Cylinder Bore Diameter](#)
Courtesy of CHRYSLER GROUP, LLC

1. Use Cylinder Indicator (special tool #C-119, Cylinder Indicator) (2) to correctly measure the inside diameter of the cylinder bore (3). A cylinder indicator capable of reading in 0.003 mm (0.0001 in.) increments is required. If a cylinder indicator is not available, do not use an inside micrometer.
2. Measure the inside diameter of the cylinder bore at a point 38.0 mm (1.5 inches) below top of bore (4). Start perpendicular (across or at 90Â°) to the axis of the crankshaft at point A and then take an additional bore reading 90Â° to that at point B.



[Fig. 108: Moly Coated Piston](#)
Courtesy of CHRYSLER GROUP, LLC

NOTE: **The coated pistons, piston pins and connecting rods are pre-assembled and serviced as an assembly.**

3. The piston and rod assembly is specific for the left cylinder bank (odd numbered) and the right cylinder bank (even numbered) and must not be interchanged.

4. The coating material (1, 2) is applied to the piston after the final piston machining process. Measuring the outside diameter of a coated piston will not provide accurate results. Therefore measuring the inside diameter of the cylinder bore with a cylinder indicator is **MANDATORY** . To correctly select the proper size piston, a cylinder indicator capable of reading in 0.003 mm (0.0001 in.) increments is required.
5. Piston installation into the cylinder bore requires slightly more pressure than that required for non-coated pistons. The bonded coating on the piston will give the appearance of a line-to-line fit with the cylinder bore.

REMOVAL

REMOVAL

CAUTION: If the engine encounters a catastrophic failure, the engine oil cooler and lines must be replaced or damage to the new engine and/or components could result.

1. Remove the cylinder head(s). Refer to **CYLINDER HEAD, REMOVAL**.
2. Remove the oil pan. Refer to **PAN, OIL, REMOVAL**.
3. If necessary, remove the ridge on top of the cylinder bores with a reliable ridge reamer before removing pistons from engine block. **Be sure to keep the tops of the pistons covered during this operation.**

CAUTION: When removing and installing the pistons and connecting rods, do not damage the piston oil cooler jets. If the jets are bent, engine damage may occur.

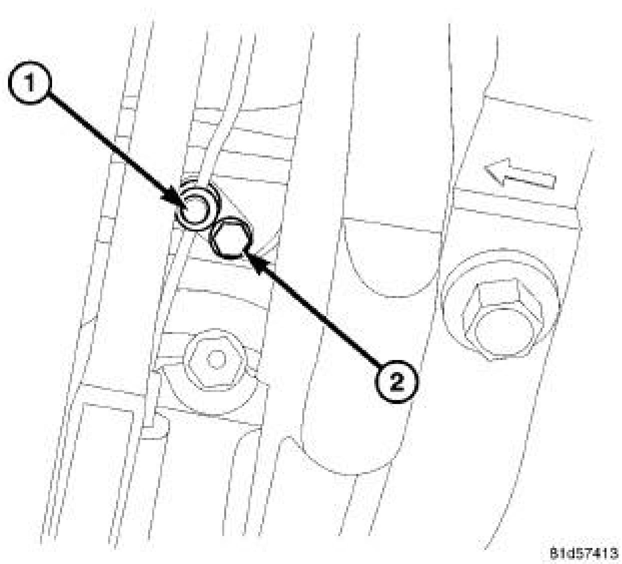


Fig. 109: Piston Oil Jet & Bolt
Courtesy of CHRYSLER GROUP, LLC

4. Remove the piston oil cooler jet(s) retaining bolt(s) (2) and remove the piston oil cooler jet(s) (1).

CAUTION: Do not use a number stamp or a punch to mark connecting rods or caps, as damage to connecting rods could occur.

CAUTION: Care must be taken not to damage the fractured rod and cap joint face surfaces as engine damage may occur.

CAUTION: Care must be taken not to nick crankshaft journals as engine damage may occur.

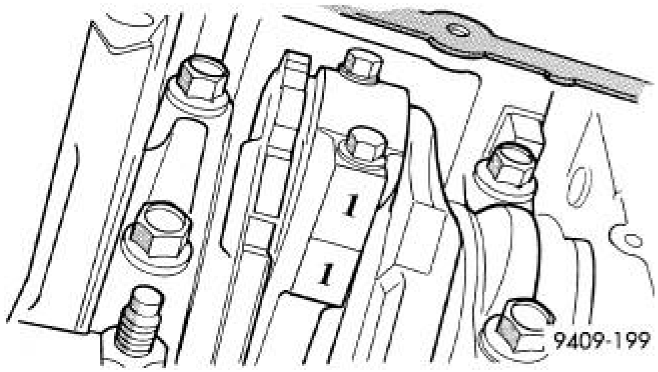

Fig. 110: Mark On Connecting Rod & Bearing Cap
Courtesy of CHRYSLER GROUP, LLC

NOTE: Connecting rods and bearing caps are not interchangeable and should be marked before removing to ensure correct reassembly.

5. Mark the connecting rod and bearing cap position using a permanent ink marker or scribe tool.

NOTE: Pistons and connecting rod assemblies must be removed from the top of the engine block. When removing the piston and connecting rod assemblies from the engine, rotate the crankshaft so each connecting rod is centered in the cylinder bore.

6. Remove the connecting rod cap and carefully remove the piston from the cylinder bore, repeat this procedure for each piston being removed.
7. Immediately after removing the piston and connecting rod, install the bearing cap on the mating connecting rod to prevent damage to the fractured cap and rod surfaces.
8. Carefully remove the piston rings from the piston(s), starting from the top ring down.

CLEANING

CLEANING

NOTE: DO NOT use a wire wheel or other abrasive cleaning devise to clean the pistons or connecting rods. The pistons have a graphite coating, this coating must not be damaged.

1. Using a suitable cleaning solvent clean the pistons in warm water and towel dry.
2. Use a wood or plastic scraper to clean the ring land grooves.

INSPECTION

INSPECTION

Check the connecting rod journal for excessive wear, taper and scoring.

Check the connecting rod for signs of twist or bending.

Check the piston for taper and elliptical shape before it is fitted into the cylinder bore. Refer to **STANDARD PROCEDURE**.

Check the piston for scoring, or scraping marks on the piston skirts. Check the ring lands for cracks and/or deterioration.

INSTALLATION

INSTALLATION

CAUTION: If the engine encounters a catastrophic failure, the engine oil cooler and lines must be replaced or damage to the new engine and/or components could result.

NOTE: Before reinstalling used rings or installing new rings, the ring clearances must be checked.

NOTE: Make sure the piston ring grooves are clean and free of nicks and burrs.

1. Check piston ring clearance. Refer to **STANDARD PROCEDURE**.
2. Before installing piston and connecting rod assemblies into the bore, install the piston rings. Refer to **STANDARD PROCEDURE**.
3. Immerse the piston head and rings in clean engine oil and position a ring compressor over the piston and rings and tighten the ring compressor. **Make sure the position of rings do not change during this operation.**

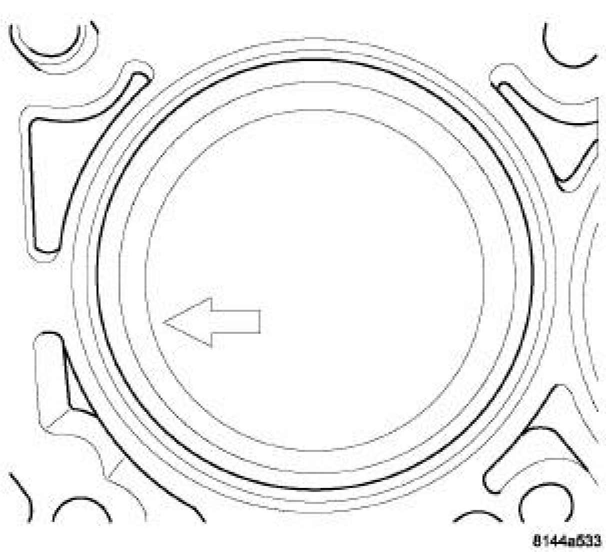

Fig. 111: Piston Direction Arrow
Courtesy of CHRYSLER GROUP, LLC

4. The pistons are marked on the piston pin bore surface with an etched "F" or arrow on top of piston indicating installation position. This mark must be pointing toward the front of the engine on both cylinder banks.
5. Wipe the cylinder bore clean and lubricate with clean engine oil.
6. Rotate the crankshaft until the connecting rod journal is centered with the cylinder bore.
7. Insert the piston and rod assembly into the cylinder bore and carefully position the connecting rod over the crankshaft journal.
8. Push the piston down in cylinder bore using a hammer handle. While at the same time, guide the connecting rod into position on crankshaft rod journal.
9. Perform the measure bearing clearance procedure. Refer to **ENGINE BLOCK, STANDARD PROCEDURE** .

10. Wipe the connecting rod cap (1) clean and lubricate with clean engine oil and install the bearing (3).

NOTE: **The connecting rods and bearing caps are not interchangeable, line up the previously marked bearing caps and connecting rods to ensure assembly to their original location.**

11. Lubricate the bearing surfaces with clean engine oil and position the rod cap onto the connecting rod.

CAUTION: **When installing the connecting rods, make sure the wide side of the connecting rod faces the crankshaft and the narrow sides face each other.**

CAUTION: **Always replace the connecting rod bolts whenever they are loosened or removed.**

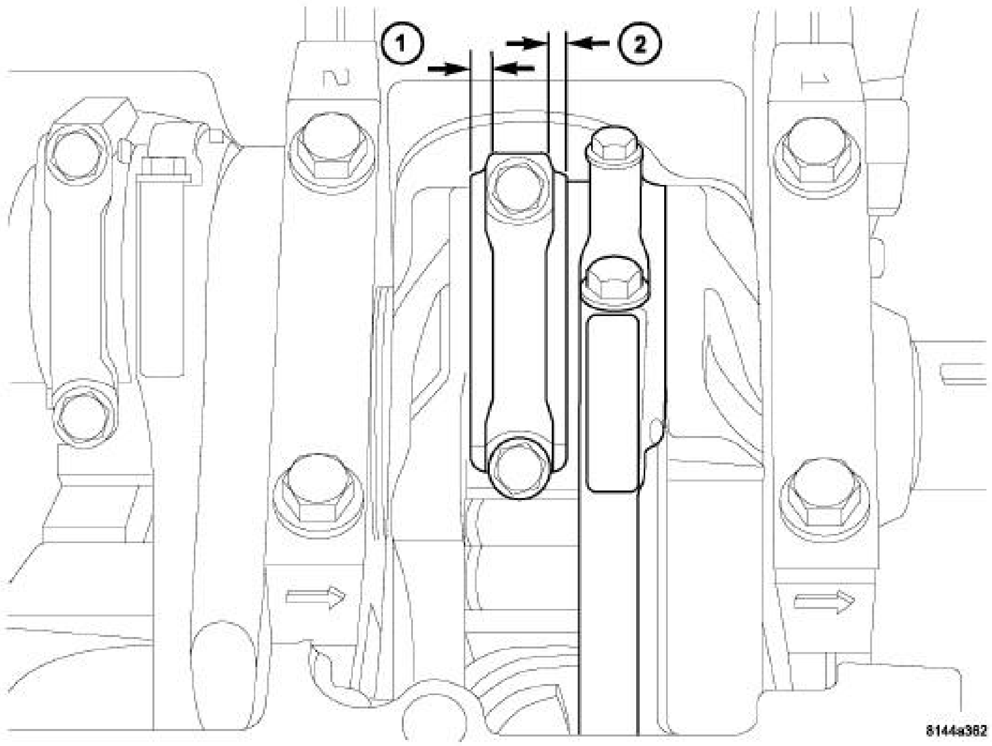

Fig. 113: Identifying Connecting Rod Proper Installation
Courtesy of CHRYSLER GROUP, LLC

12. Verify the connecting rods are properly installed, the wide side (1) of the connecting rod is facing towards the crankshaft and the narrow sides (2) of the connecting rods face each other.
13. Lubricate the new rod cap bolts with clean engine oil, install and tighten to the proper specification. Refer to TORQUE SPECIFICATIONS.

CAUTION: **When removing and installing the pistons and connecting rods, do not damage the piston oil cooler jets. If the jets are bent, engine damage may occur.**

14. Position the piston oil cooler jet(s) (1).
15. Install the piston oil cooler jet retaining bolt(s) (2) and tighten to proper specification. Refer to **TORQUE SPECIFICATIONS**.
16. Install the oil pan and oil pump pickup tube and oil pan. Refer to **PAN, OIL, INSTALLATION**.
17. Install the cylinder head(s). Refer to **CYLINDER HEAD, INSTALLATION**.
18. Connect the negative battery cable.
19. Start the engine and check for leaks.

LUBRICATION

DIAGNOSIS AND TESTING

CHECKING ENGINE OIL PRESSURE

1. Remove oil pressure sending unit and install gauge assembly (special tool #C-3292A, Gauge, Pressure).
2. Run engine until thermostat opens.
3. Check oil pressure gauge:
    - Curb Idle - 90 kPa (13 psi) minimum
    - 3000 RPM - 170 - 758 kPa (25 - 110 psi)
4. If oil pressure is 0 at idle, shut off engine. Check for a clogged oil pick-up screen or a pressure relief valve stuck open.

ENGINE OIL LEAK

Begin with a thorough visual inspection of the engine, particularly at the area of the suspected leak. If an oil leak source is not readily identifiable, the following steps should be followed:

1. Do not clean or degrease the engine at this time because some solvents may cause rubber to swell thus temporarily stopping the leak.
2. Add an oil soluble dye (use as recommended by manufacturer). Start the engine and let idle for approximately 15 minutes. Check the oil dipstick to make sure the dye is thoroughly mixed as indicated with a bright yellow color under a black light.
3. Using a black light, inspect the entire engine for fluorescent dye, particularly at the suspected area of oil leak. If the oil leak is found and identified, repair per service information procedures.
4. If dye is not observed, drive the vehicle at various speeds for approximately 24 km (15 miles), and repeat inspection.

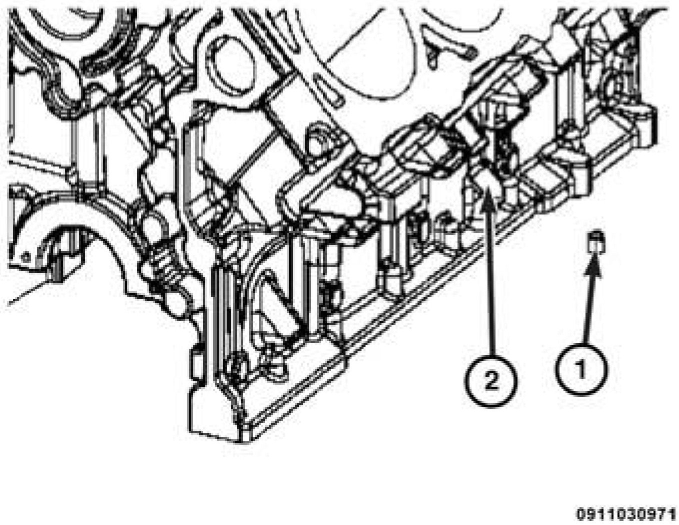

Fig. 140: Engine Oil Pan Plug Component Location
Courtesy of CHRYSLER GROUP, LLC

NOTE: **If the oil indicator tube is located in the engine oil pan. A plug (1) is inserted into the hole on the engine block (2). Validation of the plug is required when the engine block has been replaced.**

AIR LEAK DETECTION TEST METHOD

1. Remove the PCV valve, cap or plug the PCV valve port at the intake manifold.
2. Attach an air hose with a pressure gauge and regulator onto the dipstick tube.

CAUTION: **Do not subject the engine assembly to more than 20.6 kPa (3 PSI) of test pressure.**

3. Gradually apply air pressure from 1 psi to 2.5 psi maximum while applying soapy water at the suspected source. Adjust the regulator to the suitable test pressure that provide the best bubbles which will pinpoint the leak source. If the oil leak is detected and identified, repair per service information procedures.
4. If the leakage occurs at the rear oil seal area, proceed with the **INSPECTION FOR REAR SEAL AREA LEAKS**.
5. If no leaks are detected, turn off the air supply and remove the air hose from the dipstick tube.

6. Remove the PCV port plug or cap at the intake manifold and install the PCV valve.
7. Clean the oil off the suspect oil leak area using a suitable solvent. Drive the vehicle at various speeds approximately 24 km (15 miles). Inspect the engine for signs of an oil leak by using a black light. If the oil leak is found and identified, repair per service information procedures.

INSPECTION FOR REAR SEAL AREA LEAKS

Since it is sometimes difficult to determine the source of an oil leak in the rear seal area of the engine, a more involved inspection is necessary. The following steps should be followed to help pinpoint the source of the leak.

If the leakage occurs at the crankshaft rear oil seal area:

1. Disconnect and isolate the negative battery cable.
2. Raise and support the vehicle.
3. Remove torque converter or clutch housing inspection cover.
4. Using a black light and inspect the rear of the engine block for evidence of oil.

   Circular spray pattern on the rear of the engine block generally indicates:

   - Rear crankshaft oil seal
   - Damaged crankshaft

   Oil running straight down the back of the engine block generally indicates:

   - Porous engine block
   - Camshaft core hole plug
   - Oil gallery pipe plug
   - Oil pan gasket
5. If no leaks are detected, pressurize the crankcase as outlined in the **AIR LEAK DETECTION TEST METHOD**.

   CAUTION: Do not subject the engine assembly to more than 20.6 kPa (3 PSI) of test pressure.

6. If the leak is not detected, very slowly turn the crankshaft and watch for leakage. If a leak is detected between the crankshaft and crankshaft oil seal while slowly turning the crankshaft, it is possible the crankshaft seal surface is damaged. The seal area on the crankshaft could have minor nicks or scratches that can be polished out with emery cloth.

   CAUTION: Use extreme caution when crankshaft polishing is necessary to remove minor nicks and scratches. The crankshaft seal flange is machined specifically to complement the function of the rear oil seal.

7. For bubbles that remain steady with shaft rotation, no further inspection can be done until disassembled.

The 6.2L engine is equipped with Variable Valve Timing (VVT). This system uses a Variable Valve Timing Solenoid (VVTS) to control the oil pressure to direct oil pressure to the camshaft phaser assembly. The camshaft phaser assembly advances and/or retards camshaft timing to improve engine performance, mid-range torque, idle quality, fuel economy and reduce emissions. The VVTS (2) is located under the supercharger assembly.

OPERATION

OPERATION

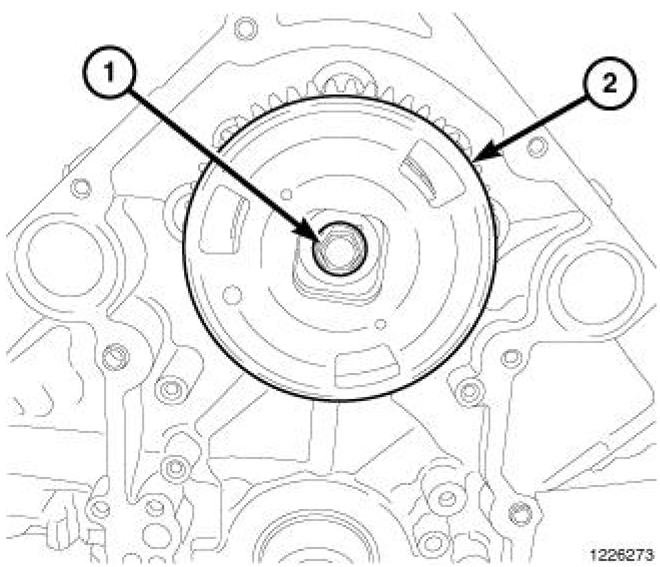

Fig. 142: Camshaft Phaser & Bolt
Courtesy of CHRYSLER GROUP, LLC

The Variable Cam Timing (VCT) assembly is actuated with engine oil pressure. The oil flow to the VCT

assembly is controlled by an Variable Valve Timing Solenoid (VVTS). The VVTS consists of a Pulse Width Modulated (PWM) solenoid and a spool valve. The Powertrain Control Module (PCM) actuates the VVTS to control oil flow through the spool valve into the VCT assembly. The VCT assembly consists of a rotor and a stator/sprocket. The stator/sprocket is connected to the timing chain. The rotor is connected to the camshaft. Oil flow into the VCT assembly rotates the rotor with respect to the stator, thus rotating the camshaft with respect to the stator/sprocket. This will rotate both the intake and exhaust lobes on the camshaft by the same amount. The intake and exhaust lobes can not be individually controlled with this VCT system. An infinitely variable valve timing position can be achieved within the limits of the hardware. The camshaft position sensor monitors the position of the camshaft with respect to the crankshaft and provides feedback to the PCM.

NOTE: The Variable Valve Timing Solenoid (VVTS) (2) is located under the supercharger assembly.

1. Remove the supercharger. Refer to **SUPERCHARGER, INSTALLATION**.
2. Disconnect VVTS electrical connector (1).
3. Remove VVTS retaining bolt (3).

NOTE: To remove the VVTS, the engine must be at room temperature.

4. Rotate the VVTS to break the seal and remove.

INSTALLATION

INSTALLATION

1. Lubricate the Variable Valve Timing Solenoid (VVTS) rubber O-ring seal with clean engine oil.

2. Install the VVTS (2) and rotate into position.
3. Install the VVTS retaining bolt (3) and tighten to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
4. Connect VVTS electrical connector (1).
5. Install the supercharger. Refer to **SUPERCHARGER, INSTALLATION**.

COOLER, OIL

DESCRIPTION

DESCRIPTION

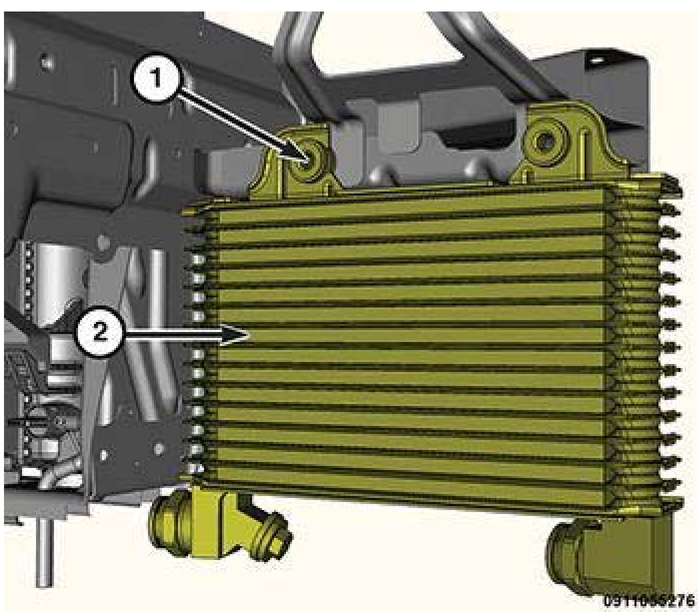

Fig. 145: Engine Oil Cooler & Retaining Bolts
Courtesy of CHRYSLER GROUP, LLC

The engine oil cooler (2) is engineered for maximum cooling efficiency with no restriction in oil flow. The oil cooler is mounted (1) behind the front fascia, on the right side of the vehicle.

The engine oil cooler uses the external air flow across cooling fins, to maintain a consistent engine oil temperature.

NOTE: **The engine oil cooler contains an additional drain plug that must be removed when changing engine oil.**

REMOVAL

REMOVAL

CAUTION: **If the engine encounters a catastrophic failure, the engine oil cooler and lines must be replaced or damage to the new engine and/or components could result.**

1. Remove the front fascia. Refer to **FASCIA, FRONT, REMOVAL** .

7. If replacing the oil filter adapter (2), remove the oil filter (1) from the oil filter adapter.
8. Remove the oil filter adapter retaining screw.

NOTE: **Whenever the oil filter adapter is serviced, the rubber O-ring seal must be replaced.**

INSTALLATION

INSTALLATION

CAUTION: **If the engine encounters a catastrophic failure, the engine oil cooler and lines must be replaced or damage to the new engine and/or components could result.**

NOTE: **Whenever the oil filter adapter is serviced, the rubber O-ring seal must be replaced.**

1. Clean the sealing surface of the oil cooler and install a new rubber O-ring seal.
2. Lightly lubricate the oil cooler rubber O-ring seal with clean engine oil.

3. Install the oil filter adapter retaining screw and tighten to the proper specification. Refer to TORQUE SPECIFICATIONS.
4. Lightly lubricate the oil filter gasket with clean engine oil.

NOTE: **Do not over tighten the oil filter.**

5. Thread the oil filter (1) onto the oil filter adapter (2) oil filter boss.
6. When the oil filter gasket makes contact with the oil cooler sealing surface, hand tighten the oil filter one half turn, or 180Ā°.

9. Connect the oil cooler lines to the quick connect fittings on the oil filter adapter (1) and the oil cooler (2).

NOTE: **Gently pull outward on each line after connected to verify a secure connection.**

10. Install the front fascia. Refer to **FASCIA, FRONT, INSTALLATION** .

11. Fill the engine oil. Refer to **STANDARD PROCEDURE**.
12. Start the engine and check for leaks.
13. Turn the engine off and check the oil level.

4. Using a suitable oil filter wrench, rotate the oil filter (2) counterclockwise to remove it from the oil filter adapter.
5. When the oil filter separates from the oil filter adapter, keep the gasket end upward to minimize oil spill and remove the oil filter from vehicle.

NOTE: **Make sure the oil filter gasket was removed with the oil filter.**

6. Using a wiping cloth, clean the oil cooler gasket sealing surface of oil and grime.

4. Position the belly pan to the under side of the vehicle and install the retainers (1).
5. Remove the support and lower the vehicle.
6. Fill the crankcase with the specified type and amount of engine oil. Refer to **STANDARD PROCEDURE**.
7. Install the oil fill cap.
8. Start the engine and check for leaks.
9. Turn the engine off and check the oil level.

JET, PISTON OIL COOLER

DESCRIPTION

DESCRIPTION

3. Install the engine oil pump pickup tube and oil pan. Refer to **PAN, OIL, INSTALLATION**.

OIL

STANDARD PROCEDURE

STANDARD PROCEDURE - ENGINE OIL SERVICE

CRANKCASE OIL LEVEL INSPECTION

The oil level indicator is located on the right side of the engine.

CAUTION: **Do not overfill crankcase with engine oil, pressure loss or oil foaming can result.**

Inspect the engine oil level approximately every 800 kilometers (500 miles). Unless the engine has exhibited loss of oil pressure, run the engine for about ten minutes before checking the oil level. Checking the engine oil level on a cold engine is not accurate.

To ensure proper lubrication of an engine, the engine oil must be maintained at an acceptable level. The acceptable levels are indicated between the ADD and SAFE marks on the engine oil level indicator.

1. Position the vehicle on the level surface.
2. With the engine off, allow approximately five minutes for the oil to settle to the bottom of the crankcase and then remove the engine oil level indicator.
3. Wipe the oil level indicator clean.
4. Install the oil level indicator and verify it is seated in the tube.

5. Remove the oil level indicator, with the handle held above the tip, observe the oil level reading.
6. Add oil only if the level is below the ADD mark on the oil level indicator.

ENGINE OIL CHANGE

Change the engine oil at the mileage and time intervals described in the Maintenance Schedules. Refer to **MAINTENANCE SCHEDULES, DESCRIPTION** .

1. Run the engine until it reaches normal operating temperature, then shut off the engine.
2. Remove the oil fill cap.
3. Raise and support the vehicle. Refer to **HOISTING, STANDARD PROCEDURE** .
4. Remove the belly pan. Refer to **BELLY PAN, REMOVAL** or **BELLY PAN, ENGINE, REMOVAL** .
5. Place a suitable drain pan under the oil pan drain.

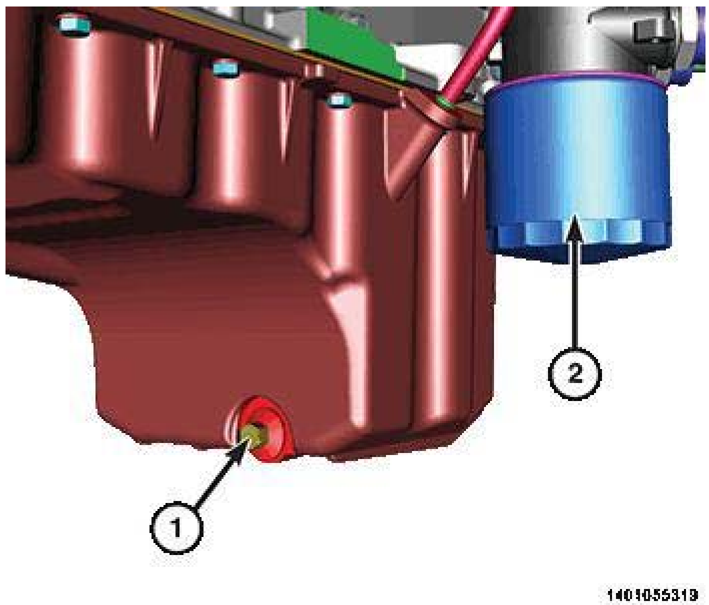

Fig. 161: Oil Pan Drain Plug & Oil Filter
Courtesy of CHRYSLER GROUP, LLC

6. Remove the drain plug (1) from the oil pan and allow the oil to drain.
7. Remove the oil filter (2).

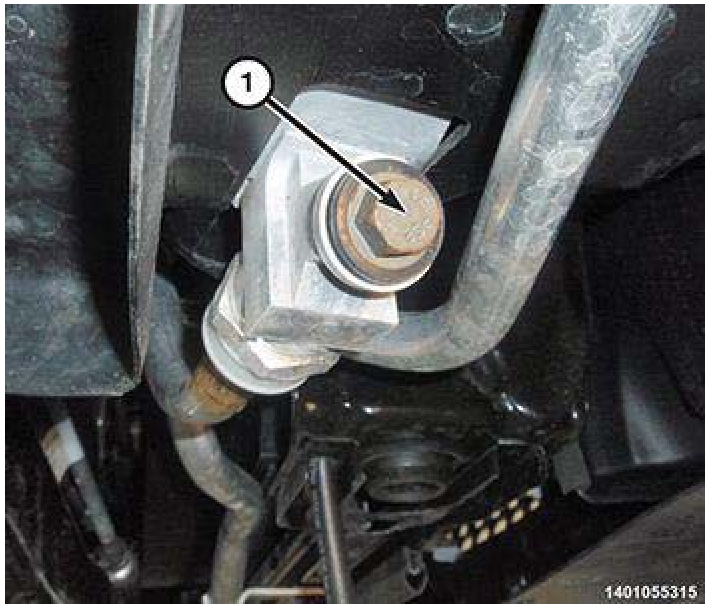

Fig. 162: Engine Oil Cooler Drain Plug

8. Place a suitable drain pan under the engine oil cooler.
9. Remove the drain plug (1) from the engine oil cooler and allow the oil to drain.

NOTE: **Allow oil to drain until there is only one drip every second, approximately five minutes.**

10. Lightly lubricate the NEW oil filter gasket with clean engine oil.
11. Fill the NEW oil filter with fresh engine oil.
12. Thread the oil filter onto the oil filter adapter.

NOTE: **Do not over tighten the oil filter.**

13. When the oil filter gasket makes contact with the oil filter adapter sealing surface, hand tighten the oil filter one half turn, or 180Â°.
14. Clean any residual oil that may have dripped onto the oil cooler hoses (3, 4).
15. Inspect the drain plug threads for stretching or other damage and replace if necessary.
16. Install both drain plugs and tighten to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
17. Install the belly pan. Refer to **BELLY PAN, INSTALLATION** or **BELLY PAN, ENGINE, INSTALLATION** .
18. Lower the vehicle and fill the crankcase with the specified type and amount of engine oil. Refer to **CAPACITIES AND RECOMMENDED FLUIDS, SPECIFICATIONS** .
19. Install the oil fill cap.
20. Start the engine and check for leaks.
21. Stop the engine and after five minutes, check the oil level.

NOTE: **Care should be exercised when disposing of used engine oil.**

NOTE: **Do not pry on the oil pan or oil pan gasket. The oil pan gasket is integral to the engine windage tray and does not come out with the oil pan.**

NOTE: **The horizontal M10 retaining bolts (11, 12, 15, 18) are 5 mm longer in length then the vertical M10 retaining bolts (20, 21, 22, 23) and must be reinstalled in their original locations.**

14. Raise and support the vehicle. Refer to **HOISTING, STANDARD PROCEDURE** .
15. Remove the M10 retaining bolts (horizontal 11, 12, 15, 18 and vertical 20, 21, 22, 23) from the rear of the oil pan to the transmission.
16. Remove the M6 retaining bolts and remove the oil pan.

NOTE: **When the oil pan is removed, a new oil pan gasket and the integral windage tray assembly must be installed, the old gasket cannot be reused.**

17. Remove the oil pump pickup tube retaining bolt and nut.
18. Remove the oil pump pickup tube.
19. Remove and discard the oil pan gasket/windage tray.

INSTALLATION

INSTALLATION

NOTE: **MoparÃ® Engine RTV must be applied to the 4 T-joints, the area where the front cover, rear retainer and oil pan gasket meet. The bead of RTV should cover the bottom of the gasket. This area is approximately 4.5 mm x 25 mm in each of the 4 T-joint locations.**

1. Clean the oil pan gasket mating surface of the engine block and oil pan.
2. Apply MoparÃ® Engine RTV at the 4 T- joints (1, 2).

   NOTE: **When the oil pan is removed a NEW oil pan gasket and the integral windage tray assembly must be installed, the old gasket cannot be reused.**

3. Install a NEW oil pan gasket/windage tray.
4. Using a NEW O-ring, position the oil pump pickup tube into the oil pump.
5. Install the oil pump pickup tube retaining bolt and nut and tighten to the proper specification. Refer to TORQUE SPECIFICATIONS.

NOTE: **NEW M6 retaining bolts must be used when reinstalling the oil pan. Do not reuse the old M6 retaining bolts.**

6. Align the rear of the oil pan with the rear face of the engine block and install the M10 and M6 retaining bolts finger tight.
7. Using the sequence shown in illustration, tighten the M6 retaining bolts to 5 N.m (44 in. lbs.).
8. Using the sequence shown in illustration, tighten the M10 retaining bolts to 54 N.m (40 ft. lbs.).
9. Using the sequence shown in illustration, tighten the M6 retaining bolts to 12 N.m (9 ft. lbs.).

CAUTION: Oil pump pressure relief valve and spring should not be removed from the oil pump. If these components are disassembled and or removed from the pump the entire oil pump assembly must be replaced.

1. Remove the pump cover.
2. Clean all parts thoroughly. The mating surface of the oil pump housing should be smooth. If the oil pump cover is scratched or grooved the oil pump assembly should be replaced.
3. Slide the outer rotor into the body of the oil pump. Press the outer rotor to one side of the oil pump body and measure the clearance between the outer rotor (2) and the body. If the measurement is 0.306 mm (0.012 in.) or greater the oil pump assembly must be replaced.

SENSOR, OIL PRESSURE

DESCRIPTION

DESCRIPTION

The oil pressure sensor uses the following three circuits:

- Signal circuit to the PCM
- Sensor ground circuit through the PCM
- 5 volt reference circuit from the PCM

The oil pressure sensor returns a voltage signal back to the PCM with reference to oil pressure. Ground for the sensor is supplied by the PCM.

The oil pressure sensor is located on the right side of the engine block. The sensor screws into the engines main oil gallery.

REMOVAL

REMOVAL

1. Remove the generator. Refer to **GENERATOR, REMOVAL** .
2. Position the generator aside to gain access to the oil pressure sensor.

SENSOR, OIL TEMPERATURE

DESCRIPTION

DESCRIPTION

The oil temperature sensor uses the following two circuits:

- Signal circuit to the PCM
- Ground circuit from the PCM

The oil temperature sensor is a Negative Thermal Coefficient sensor. The resistance of the sensor changes as oil temperature changes. This results in different output voltages back to the PCM.

The oil temperature sensor is located on the right side of the engine block.

REMOVAL

REMOVAL

1. Remove the generator. Refer to **GENERATOR, REMOVAL** .
2. Position the generator aside to gain access to the oil temperature sensor.

DESCRIPTION

DESCRIPTION

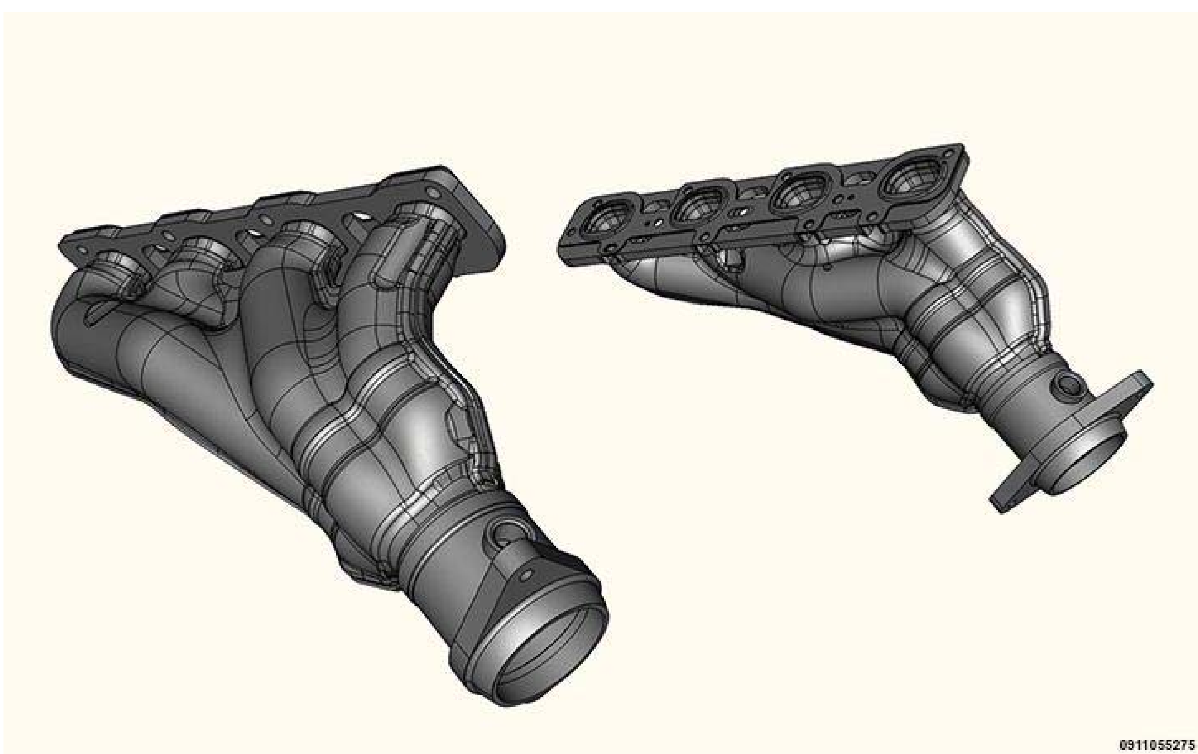

Fig. 192: Exhaust Manifolds

Courtesy of CHRYSLER GROUP, LLC

The exhaust manifolds are tube in shell air gap design to maximize durability and performance. The exhaust manifolds are made of stainless steel stamped shells and stainless steel tubes with a powdered metal outlet. A layered graphite over perforated steel manifold gasket is used to provide sealing to the cylinder head.

OPERATION

OPERATION

The exhaust manifolds collect the engine exhaust gases exiting the combustion chambers and then channels the exhaust gases to the exhaust pipes/catalytic converters.

REMOVAL

REMOVAL

NOTE: The left side shown in illustration. Right side similar.

1. Disconnect and isolate the negative battery cable.
2. Remove cylinder head. Refer to **CYLINDER HEAD, REMOVAL**.

6. Connect the negative battery cable.
7. Start the engine and check for leaks.

SUPERCHARGER SYSTEM

BELT, DRIVE

DESCRIPTION

DESCRIPTION

The supercharger drive belt is a serpentine type belt. The supercharger drive belt is separate from the accessory drive belt. Satisfactory performance of these belts depends on belt condition and proper belt tension.

REMOVAL

REMOVAL

1. Remove the accessory drive belt. Refer to **BELT, SERPENTINE, REMOVAL** .

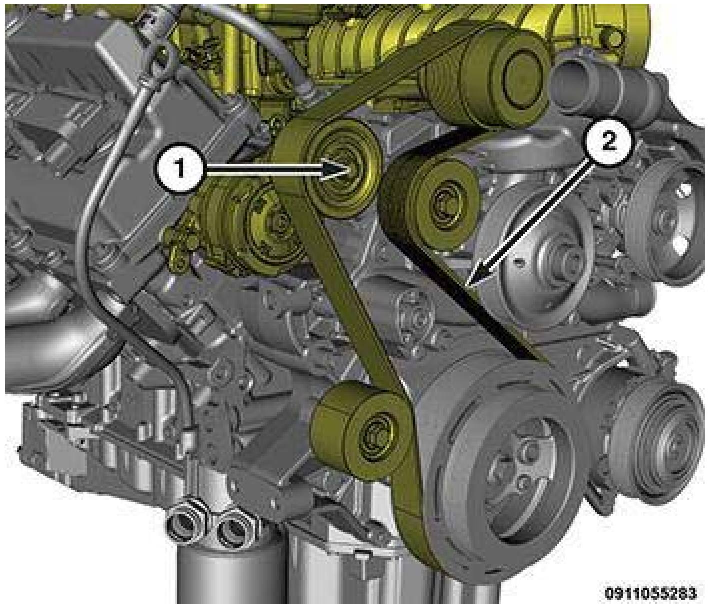

Fig. 195: Belt & Tensioner
Courtesy of CHRYSLER GROUP, LLC

2. Release the belt tension by rotating the tensioner (1) **clockwise** . Rotate the belt tensioner until the belt (2) can be removed from pulleys.
3. Remove the belt.
4. Gently release the tensioner.

SUPERCHARGER

DESCRIPTION

DESCRIPTION

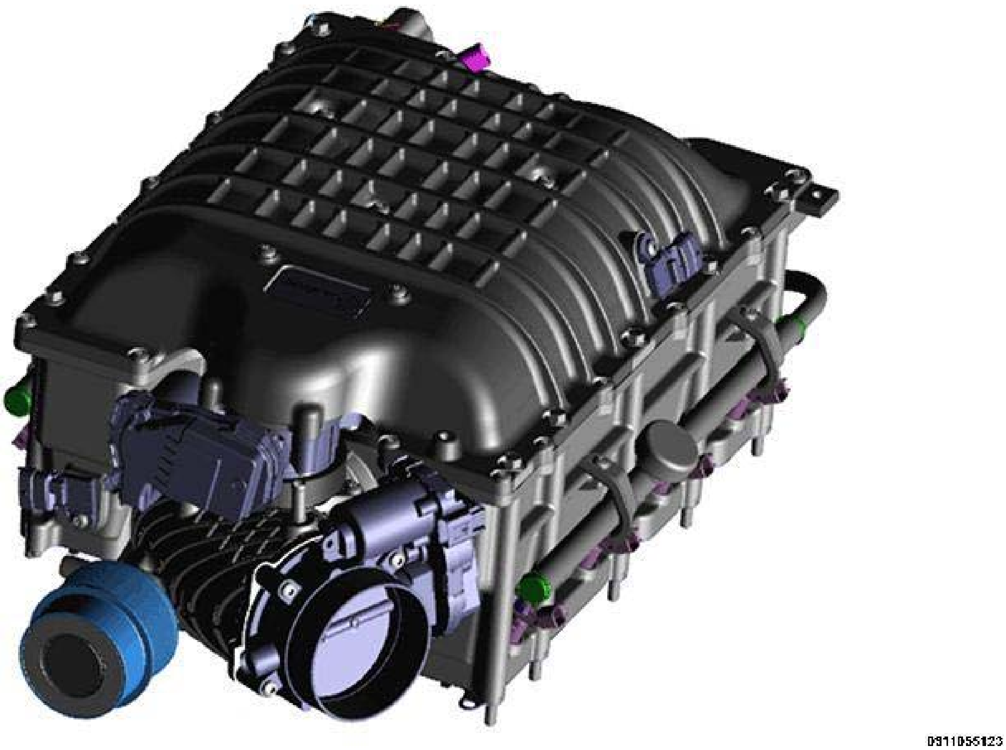

Fig. 202: Supercharger

The twin-screw supercharger has integral charge air coolers and an integrated 64 mm electronic bypass valve to regulate boost pressure. The supercharger is sealed for life with synthetic oil, has a drive ratio of 2.36:1 and a maximum speed of 14, 600 RPM. The one-way clutch de-coupler improves refinement without detracting from the engine noise. The supercharger intakes air through a 92 mm throttle body.

20. Remove the supercharger to cylinder head retaining bolts, starting with number ten, going backwards to number one.

NOTE: **The supercharger assembly will require the help of an assistant(s) to lift from the engine compartment.**

21. Lift the supercharger upward to disengage the dowels which align the supercharger to the right cylinder head.

NOTE: **Take care not to damage supercharger to cylinder head intake gaskets during removal.**

INSTALLATION

INSTALLATION

NOTE: **The supercharger assembly will require the help of an assistant(s) to install the assembly into the engine compartment.**

1. Inspect the seals and replace if necessary.
2. Position the supercharger assembly onto the cylinder heads, aligning the dowels in the supercharger with the holes cylinder head.

The timing chain tensioner is a spring loaded design. It consists of two chain guide shoes. One shoe is fixed in place and the other is spring loaded to keep tension on the chain.

OPERATION

OPERATION

The timing chain tension is maintained by routing the timing chain through the tensioner assembly. The tensioner assembly consists of two chain guide shoes. One shoe is fixed in place and the other is spring loaded to maintain the correct timing chain tension.

2015-16 ENGINE

6.4L - Service Information - Challenger

DESCRIPTION

DESCRIPTION

CAUTION: If the engine has experienced a catastrophic failure, THE INTAKE MANIFOLD MUST BE REPLACED!

The 6.4L HEMI eight-cylinder SRT high performance engine is a 90Â° V-Type, deep skirt, lightweight cast iron block with aluminum heads, single cam, overhead valves, and hydraulic roller lifters. The heads incorporate splayed valves with a hemispherical style combustion chamber and dual spark plugs. The cylinders are numbered from front to rear; 1, 3, 5, 7 on the left bank and 2, 4, 6, 8 on the right bank. The firing order is 1-8-4-3-6-5-7-2. The 6.4L HEMI engine is a bored and stroked version of the 5.7L HEMI engine developed for SRT high performance vehicles.

DIAGNOSIS AND TESTING

CYLINDER COMBUSTION PRESSURE LEAKAGE

The combustion pressure leakage test provides an accurate means for determining engine condition.

Combustion pressure leakage testing will detect:

- Exhaust and intake valve leaks (improper seating)
- Leaks between adjacent cylinders or into water jacket
- Any causes for combustion pressure loss

1. Check the coolant level and fill as required. DO NOT install the radiator cap.
2. Start and operate the engine until it attains normal operating temperature.
3. Turn the engine OFF.
4. Remove one spark plug per cylinder.
5. Remove the oil filler cap.
6. Remove the air cleaner hose.
7. **Calibrate the tester according to the manufacturer's instructions.** The shop air source for testing should maintain a regulated air pressure at 552 kPa (80 psi).
8. Perform the test procedures on each cylinder according to the tester manufacturer's instructions. Set the piston of the cylinder to be tested at TDC compression.
9. During the testing, listen for pressurized air escaping through the throttle body, tailpipe and oil filler cap opening. Check for bubbles in the radiator coolant.

All gauge pressure indications should be equal, with **no more** than 25% leakage.

FOR EXAMPLE: Input air at 552 kPa (80 psi), the primary gauge factory set at 207 kPa (30 psi) input

pressure. The secondary gauge should have no more than 176 kPa (25.5 psi) loss, when connected to the cylinder.

Refer to **CYLINDER COMBUSTION PRESSURE LEAKAGE DIAGNOSIS CHART**.

CYLINDER COMBUSTION PRESSURE LEAKAGE DIAGNOSIS CHART

CONDITION	POSSIBLE CAUSE	CORRECTION
Air escapes through the throttle body	Intake valve bent, burnt, or not seated properly.	Inspect valve and valve seat. Reface or replace, as necessary. Inspect valve springs. Replace as necessary.
Air escapes through the tailpipe	Exhaust valve bent, burnt, or not seated properly.	Inspect valve and valve seat. Reface or replace, as necessary. Inspect valve springs. Replace as necessary.
Air escapes through the radiator	Cylinder head gasket leaking or cracked in cylinder head or engine block.	Remove cylinder head and inspect. Replace cylinder head gasket, cylinder head or engine block as necessary.
More than 50% leakage from adjacent cylinders	Cylinder head gasket leaking or crack in cylinder head or engine block between adjacent cylinders.	Remove cylinder head and inspect. Replace cylinder head gasket, cylinder head or engine block as necessary.
More than 25% leakage and air escapes through the oil filler cap opening only	Stuck or broken piston rings; cracked piston; worn rings or cylinder wall.	Remove cylinder head and inspect for broken rings or piston. Measure ring gap and cylinder diameter, taper and out-of-round. Replace defective part as necessary.

CYLINDER COMPRESSION PRESSURE LEAKAGE

NOTE: **The results of a cylinder compression pressure test can be utilized to diagnose several engine malfunctions.**

NOTE: **Ensure the battery is completely charged and the engine starter motor is in good operating condition. Otherwise the indicated compression pressures may not be valid for diagnosis purposes.**

1. Clean the spark plug recesses with compressed air.
2. Remove the spark plugs and record the cylinder number of each spark plug for future reference.
3. Inspect the spark plug electrodes for abnormal firing indicators such as fouled, hot, oily, etc.
4. Perform the fuel system pressure release procedure. Refer to **FUEL DELIVERY, GAS, STANDARD PROCEDURE** .
5. Insert a compression pressure gauge and rotate the engine with the engine starter motor for three revolutions.
6. Record the compression pressure on the 3rd revolution. Continue the test for the remaining cylinders.

NOTE: **The recommended compression pressures are to be used only as a guide**

to diagnosing engine problems. An engine should not be disassembled to determine the cause of low compression unless some malfunction is present.

7. Compression should not be less than 689 kPa (100 psi) and not vary more than 25 percent from cylinder to cylinder.
8. If one or more cylinders have abnormally low compression pressures, repeat the compression test.

NOTE: **If the same cylinder or cylinders repeat an abnormally low reading on the second compression test, it could indicate the existence of a problem in the cylinder in question.**

9. If one or more cylinders continue to have abnormally low compression pressures, perform the cylinder combustion pressure leakage test. Refer to **CYLINDER COMBUSTION PRESSURE LEAKAGE**.

ENGINE MECHANICAL DIAGNOSIS CHART

CONDITION	POSSIBLE CAUSES	CORRECTION
ENGINE NOISE	1. Worn accessory drive belt	1. Check for belt damage and alignment Refer to **BELT, SERPENTINE, DIAGNOSIS AND TESTING** .
	2. Worn coolant pump	2. Check for possible coolant leak. If OK, Check the pulley and input shaft for wear. Replace as necessary.
	3. Worn generator	3. Check the pulley for wear. Spin the armature. Replace as necessary.
	4. Idler/Tensioner pulley	4. Check pulleys. Verify bearing noise. Replace as necessary.
	5. Power steering pump (if equipped)	5. Check the pulley and input shaft for wear. Replace as necessary.
	6. Flywheel/Flexplate	6. Check for wear or possible cracking. Check bolts. Repair as necessary.
NOISY VALVES/LIFTERS	1. High or low oil level in crankcase.	1. Check for correct oil level. Adjust oil level by draining or adding as needed.
	2. Thin or diluted oil.	2. Change oil. Refer to **STANDARD PROCEDURE**.
	3. Low oil pressure.	3. Check engine oil level. If OK, perform oil pressure test. Refer to **DIAGNOSIS AND TESTING**.
	4. Dirt in hydraulic lifters.	4. Clean/replace hydraulic lifters.

CONDITION	POSSIBLE CAUSES	CORRECTION
	5. Bent push rod(s).	5. Install new push rods.
	6. Worn rocker arms.	6. Inspect oil supply to rocker arms and replace worn arms as needed.
	7. Worn hydraulic lifters.	7. Install new hydraulic lifters.
	8. Worn valve guides.	8. Inspect all valve guides and replace as necessary.
	9. Excessive runout of valve seats or valve faces.	9. Grind valves and seats.
CONNECTING ROD NOISE	1. Insufficient oil supply.	1. Check engine oil level.
	2. Low oil pressure.	2. Check engine oil level. If OK, perform oil pressure test. Refer to **DIAGNOSIS AND TESTING**.
	3. Thin or diluted oil.	3. Change oil to correct viscosity. Refer to **STANDARD PROCEDURE**.
	4. Excessive connecting rod bearing clearance.	4. Measure bearings for correct clearance with plasti-gage. Repair as necessary.
	5. Connecting rod journal out of round.	5. Replace crankshaft or grind journals.
	6. Misaligned connecting rods.	6. Replace bent connecting rods.
MAIN BEARING NOISE	1. Insufficient oil supply.	1. Check engine oil level.
	2. Low oil pressure.	2. Check engine oil level. If OK, perform oil pressure test. Refer to **DIAGNOSIS AND TESTING**.
	3. Thin or diluted oil.	3. Change oil to correct viscosity. Refer to **STANDARD PROCEDURE**.
	4. Excessive main bearing clearance.	4. Measure bearings for correct clearance. Repair as necessary.
	5. Excessive end play.	5. Check crankshaft thrust bearing for excessive wear on flanges.
	6. Crankshaft main journal out of round or worn.	6. Grind journals or replace crankshaft.
	7. Loose flexplate, flywheel or torque converter.	7. Inspect crankshaft, flexplate, flywheel and bolts for damage. Tighten to correct torque specification.
LOW OIL PRESSURE	1. Low oil level.	1. Check oil level and fill if necessary.
	2. Faulty oil pressure sending unit.	2. Install new sending unit.

CONDITION	POSSIBLE CAUSES	CORRECTION
	3. Clogged oil filter.	3. Install new oil filter.
	4. Worn oil pump.	4. Replace oil pump assembly.
	5. Thin or diluted oil.	5. Change oil to correct viscosity. Refer to **STANDARD PROCEDURE**.
	6. Excessive bearing clearance.	6. Measure bearings for correct clearance.
	7. Oil pump relief valve stuck.	7. Remove valve to inspect, clean and reinstall.
	8. Oil pickup tube loose, broken, bent or clogged.	8. Inspect oil pickup tube and pump, and clean or replace if necessary.
	9. Oil pump cover warped or cracked.	9. Install new oil pump.
	10. Faulty or missing piston cooling jets.	10. Replace piston cooling jets.
OIL LEAKS	1. Misaligned or deteriorated gaskets.	1. Replace gasket.
	2. Loose fastener or broken or porous metal part.	2. Tighten, repair or replace the part.
	3. Front or rear crankshaft oil seal leaking.	3. Replace seal.
	4. Leaking oil gallery plug or cup plug.	4. Remove and reseal threaded plug. Replace cup style plug.
EXCESSIVE OIL CONSUMPTION OR SPARK PLUGS OIL FOULED	1. PCV System malfunction.	1. Refer to **VALVE, POSITIVE CRANKCASE VENTILATION (PCV), REMOVAL** .
	2. Defective valve stem seal(s).	2. Repair or replace seal(s).
	3. Worn or broken piston rings.	3. Hone cylinder bores. Install new rings.
	4. Scuffed pistons/cylinder walls.	4. Hone cylinder bores and replace pistons as required.
	5. Carbon in oil control ring groove.	5. Remove rings and de-carbon piston.
	6. Worn valve guides.	6. Inspect/replace valve guides as necessary.
	7. Piston rings fitted too tightly in grooves.	7. Remove rings and check ring end gap and side clearance. Replace if necessary.

Lifter Purge Guideline

1. Warm engine to standard idle conditions.

NOTE: **Engine noise may be in the form of a clicking, chatter, or clattering noise.**

2. Listen to the engine for 30 to 60 seconds with the hood up and the engine cover removed.
3. If noise is present, de-aeration of the lifters is required.
4. Run the engine between 2000 and 3000 RPM for three to five minutes.
5. Return the engine to standard idle speed for 30 to 60 seconds.
6. Evaluate noise. If noise is present, repeat the run an additional 4 cycles.

NOTE: **The standard drive cycle will be about 10-15 miles of non-stop, combined highway and city driving.**

7. If noise is present, take the vehicle on a standard drive cycle.
8. Evaluate the noise. If noise present, follow standard service procedure for lifter repairs or noise conditions.
9. Evaluate the lifters for sponginess, check valve defects, and clearance.

ENGINE LUBRICATION DIAGNOSTIC TABLE

CONDITION	POSSIBLE CAUSES	CORRECTION
OIL LEAKS	1. Gaskets and O-rings • Misaligned or damaged • Loose fasteners, broken or porous metal parts 2. Crankshaft rear seal 3. Crankshaft seal flange damaged 4. Oil pan flange cracked 5. OIL PUMPING AT RINGS; SPARK PLUGS FOULING	1. Worn or damaged rings 2. Carbon in oil ring slots 3. Incorrect ring size installed 4. Worn valve guides 5. Leaking intake gasket 6. Leaking valve guide seals	1. Hone cylinder bores and replace rings 2. Replace rings 3. Replace rings 4. Ream guides and replace valves 5. Replace intake gaskets 6. Replace valve guide seals

OIL CONSUMPTION TEST AND DIAGNOSIS

The following diagnostic procedures are used to determine the source of excessive internal oil consumption, these procedures and tests apply to vehicles with 50, 000 miles or less.

NOTE: **Engine oil consumption may be greater than normal during engine break-in. Repairs should be delayed until vehicle has been driven at least 7, 500 miles.**

Severe service (high ambient temperature, short trips, heavy loading, trailer towing, taxi, off-road, or law enforcement use) may result in greater oil consumption than normal.

Sustained high speed driving and high engine RPM operation may result in increased oil consumption.

Failure to comply with the recommended oil type and viscosity rating, as outlined in the owner's manual, may impact oil economy as well as fuel economy.

Oil consumption may increase with vehicle age and mileage due to normal engine wear.

NOTE: **Because a few drops of external oil leakage per mile can quickly account for the loss of one quart of oil in a few hundred miles, verify that no external engine oil leaks are present.**

- **Oil leakage is not the same as oil consumption and all external leakage must be eliminated before any action can be taken to verify and correct oil consumption complaints.**
- **Verify that the engine has the correct oil level dipstick and dipstick tube installed.**
- **Verify that the engine is not being run in an overfilled condition. Check the oil level 15 minutes after a hot shutdown with the vehicle parked on a level surface. In no case should the level be above MAX or the FULL mark on the dipstick.**

OIL CONSUMPTION TEST

1. Check the oil level at least 15 minutes after a hot shutdown.
2. If the oil level is low, top off with the proper viscosity and API service level engine oil. Add one bottle of MOPARĀ® 4-In-1 Leak Detection Dye into the engine oil.
3. Tamper proof the oil pan drain plug, oil filter, dipstick and oil fill cap.

4. Record the vehicle mileage.
5. Instruct the customer to drive the vehicle as usual.
6. Ask the customer to return to the servicing dealer after accumulating 500 miles, Check the oil level at least 15 minutes after a hot shutdown. If the oil level is half way between the "FULL" and "ADD" mark continue with the next step.
7. Using a black light, recheck for any external engine oil leaks, repair as necessary, if no external engine oil leaks are present, continue with oil consumption diagnosis.

OIL CONSUMPTION DIAGNOSIS

1. Check the Positive Crankcase Ventilation (PCV) system. Make sure the system is not restricted and the PCV valve has the correct part number and correct vacuum source (18-20 in. Hg at idle below 3000 ft. above sea level is considered normal).
2. Perform a cylinder compression test and cylinder leak down test using the standard leak down gauge following manufacturers suggested best practices. Refer to **CYLINDER COMPRESSION PRESSURE LEAKAGE** and **CYLINDER COMBUSTION PRESSURE LEAKAGE**.

NOTE: **Verify the spark plugs are not oil saturated. If the spark plugs are oil saturated and compression is good it can be assumed the valve seals or valve guides are at fault.**

3. If one or more cylinders have more than 15% leak down further engine tear down and inspection will be required.

TOP 18 REASONS THAT MAY LEAD TO ENGINE OIL CONSUMPTION

1. **Tapered and Out-of-Round Cylinders**

   The increased piston clearances permit the pistons to rock in the worn cylinders. While tilted momentarily, an abnormally large volume of oil is permitted to enter on one side of the piston. The rings, also tilted in the cylinder, permit oil to enter on one side. Upon reversal of the piston on each stroke, some of this oil is passed into the combustion chamber.

2. **Distorted Cylinders**

   This may be caused by unequal heat distribution or unequal tightening of cylinder head bolts. This condition presents a surface which the rings may not be able to follow completely. In this case, there may be areas where the rings will not remove all of the excess oil. When combustion takes place, this oil will be burned and cause high oil consumption.

3. **Improper operation of the PCV system**

   The main purpose of the Positive Crankcase Ventilation (PCV) valve is to recirculate blow-by gases back from the crankcase area through the engine to consume unburned hydrocarbons. The PCV system usually has a one way check valve and a make up air source. The system uses rubber hoses that route crankcase blow by gases to the intake manifold. Vacuum within the engine intake manifold pulls the blow by gases out of the crankcase into the combustion chamber along with the regular intake air and fuel mixture.

   The PCV system can become clogged with sludge and varnish deposits and trap blow by gases in the

crankcase. This degrades the oil, promoting additional formation of deposit material. If left uncorrected, the result is plugged oil rings, oil consumption, rapid ring wear due to sludge buildup, ruptured gaskets and seals due to crankcase pressurization.

4. **Worn Piston Ring Grooves**

   For piston rings to form a good seal, the sides of the ring grooves must be true and flat - not flared or shouldered. Piston rings in tapered or irregular grooves will not seal properly and, consequently, oil will pass around behind the rings into the combustion chamber.

5. **Worn, Broken or Stuck Piston Rings**

   When piston rings are broken, worn or stuck to such an extent that the correct tension and clearances are not maintained, this will allow oil to be drawn into the combustion chamber on the intake stroke and hot gases of combustion to be blown down the cylinder past the piston on the power stroke. All of these conditions will result in burning and carbon build up of the oil on the cylinders, pistons and rings.

6. **Cracked or Broken Ring Lands**

   Cracked or broken ring lands prevent the rings from seating completely on their sides and cause oil pumping. This condition will lead to serious damage to the cylinders as well as complete destruction of the pistons and rings. Cracked or broken ring lands cannot be corrected by any means other than piston replacement.

7. **Worn Valve Stems and Guides**

   When wear has taken place on valve stems and valve guides, the vacuum in the intake manifold will draw oil and oil vapor between the intake valve stems and guides into the intake manifold and then into the cylinder where it will be burned.

8. **Bent or Misaligned Connecting Rods**

   Bent or misaligned connecting rods will not allow the pistons to ride straight in the cylinders. This will prevent the pistons and rings from forming a proper seal with the cylinder walls and promote oil consumption. In addition, it is possible that a bearing in a bent connect rod will not have uniform clearance on the connecting rod wrist pin. Under these conditions, the bearing will wear rapidly and throw off an excessive amount of oil into the cylinder.

9. **Fuel Dilution**

   If raw fuel is allowed to enter the lubrication system, the oil will become thinner and more volatile and will result in higher oil consumption. The following conditions will lead to higher oil consumption;

   - Excess fuel can enter and mix with the oil via a leaking fuel injector
   - Gasoline contaminated with diesel fuel
   - Restricted air intake
   - Excessive idling

10. **Contaminated Cooling Systems**

Corrosion, rust, scale, sediment or other formations in the water jacket and radiator will prevent a cooling system from extracting heat efficiently. This is likely to cause cylinder distortion thus leading to higher oil consumption.

11. **Oil Viscosity**

    The use of oil with a viscosity that is too light may result in high oil consumption. Refer to the vehicle owner's manual for the proper oil viscosity to be used under specific driving conditions and ambient temperatures.

12. **Dirty Engine Oil**

    Failure to change the oil and filter at proper intervals may cause the oil to be so dirty that it will promote accumulation of sludge and varnish and restrict oil passages in the piston rings and pistons. This will increase oil consumption; dirty oil by nature is also consumed at a higher rate than clean oil.

13. **Crankcase Overfull**

    Due to an error in inserting the oil dip stick so that it does not come to a seat on its shoulder, a low reading may be obtained. Additional oil may be added to make the reading appear normal with the stick in this incorrect position which will actually make the oil level too high. If the oil level is so high that the lower ends of the connecting rods touch the oil in the oil pan excessive quantities of oil will be thrown on the cylinder walls and some of it will work its way up into the combustion chamber.

14. **Excessively High Oil Pressure**

    A faulty oil pressure relief valve may cause the oil pressure to be too high. The result will be that the engine will be flooded with an abnormally large amount of oil in a manner similar to that which occurs with worn bearings. This condition may also cause the oil filter to burst.

15. **Aftermarket Performance Chips and Modification**

    Increasing performance through the use of performance/power enhancement products to a stock or factory engine will increase the chance of excessive oil consumption.

16. **Lugging Engine**

    Lugging is running the engine at a lower RPM in a condition where a higher RPM (more power/torque) should be implemented. Especially susceptible on vehicles equipped with a manual transmission. This driving habit causes more stress loading on the piston and can lead to increases in engine oil consumption.

17. **Turbocharged Engines**

    There is a possibility for PCV "push-over" due to higher crankcase pressure (as compared to naturally aspirated engines) which is normal for turbocharged engines. This condition causes varying amounts of engine oil to enter the intake manifold, charge air cooler and associated plumbing to and from the charge air cooler, also a leaking turbocharger seal will draw oil into the combustion chamber where it will burn (blue smoke from the tail pipe may be present) and form carbon deposits which contribute to further oil consumption as they interfere with proper engine function.

18. **Restricted Air Intake**

    Excessive restriction in the air intake system will increase engine vacuum and can increase oil consumption. An extremely dirty air filter would be one example of this situation.

STANDARD PROCEDURE

DUST COVERS AND CAPS

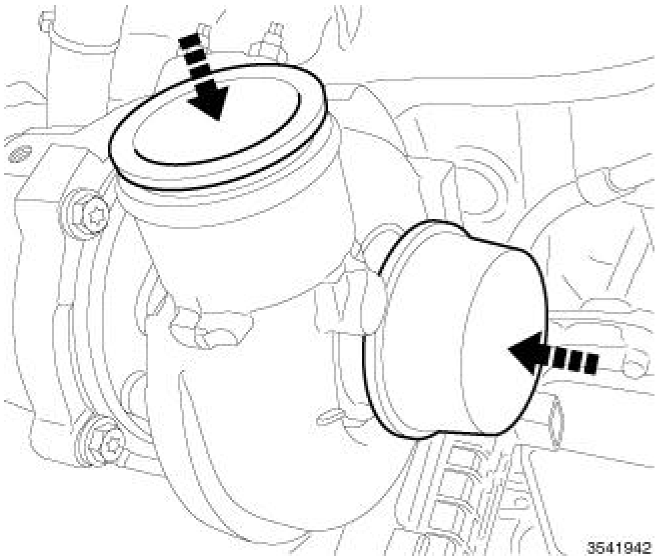

Fig. 1: Covers/Caps
Courtesy of CHRYSLER GROUP, LLC

To avoid the possibility of dust, dirt, moisture and other foreign debris being introduced to the engine during service, cover or cap all openings when hoses and tubes are removed.

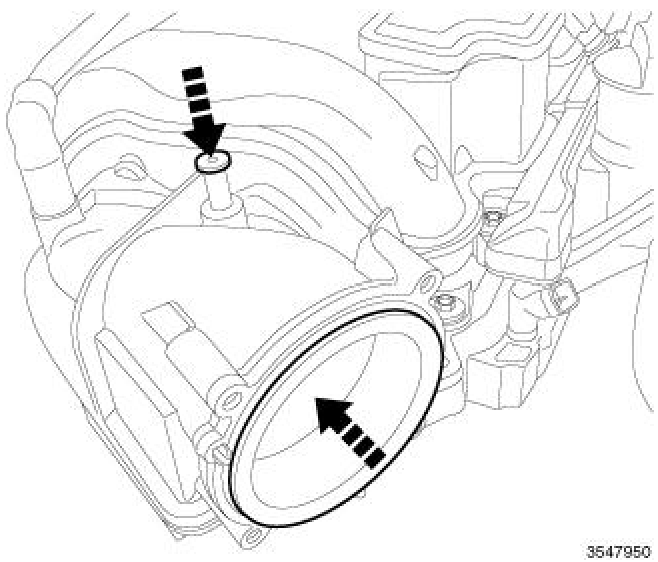

Fig. 2: Opening Cover
Courtesy of CHRYSLER GROUP, LLC

Covers installed over openings will reduce the possibility of foreign materials to entering the engine systems. Using miller tool Universal Protective Cap Set (special tool #10368, Set, Universal Protective Cap), select the

appropriate cover needed for the procedure.

ENGINE GASKET SURFACE PREPARATION

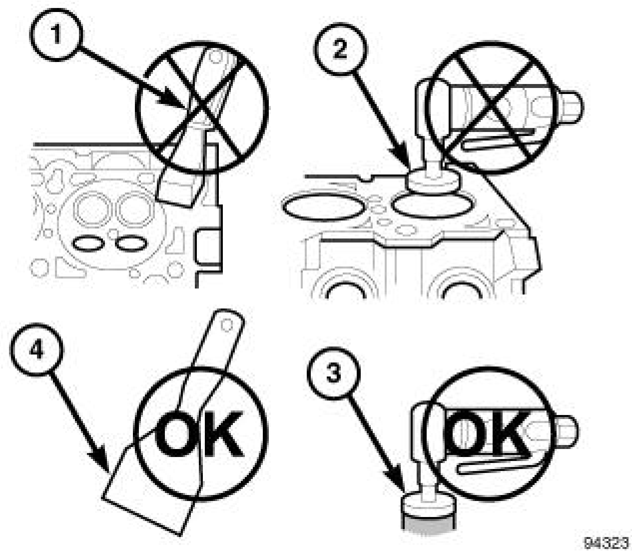

Fig. 3: Proper Tool Usage For Surface Preparation
Courtesy of CHRYSLER GROUP, LLC

To ensure engine gasket sealing, proper surface preparation must be performed, especially with the use of aluminum engine components and multi-layer steel cylinder head gaskets.

Never use the following to clean gasket surfaces:

- Metal scraper (1).
- Abrasive pad or paper to clean cylinder block and head.
- High speed power tool with an abrasive pad or a wire brush (2).

NOTE: Multi-Layer Steel (MLS) head gaskets require a scratch free sealing surface.

Only use the following for cleaning gasket surfaces:

- Solvent or a commercially available gasket remover
- Plastic or wood scraper (4).
- Drill motor with 3M Roloc™ Bristle Disc (3), white is used for the aluminum heads and yellow is used for the iron block.

CAUTION: Excessive pressure or high RPM (beyond the recommended speed), can damage the sealing surfaces. The mild (white, 120 grit) bristle disc is recommended. If necessary, the medium (yellow, 80 grit) bristle disc may be used on cast iron surfaces with care.

HYDROSTATIC LOCK

CAUTION: Do not attempt to run engine. Severe damage could occur.

When an engine is suspected of hydrostatic lock (regardless of what caused the problem), follow the steps below.

1. Disconnect and isolate the negative battery cable.
2. Lift the engine cover retaining grommets off the ball studs and remove the engine cover.
3. Place a shop towel around the fuel supply line quick connect fitting to catch any fuel that may be under pressure, then disconnect the fuel supply line. Refer to **FITTING, QUICK CONNECT, STANDARD PROCEDURE** .
4. Loosen the air duct retaining clamp at the throttle body.
5. Disconnect the intake air temperature sensor electrical connector.
6. Remove the makeup air hose at the air cleaner housing.
7. Remove the air cleaner housing retaining bolt.
8. While lifting up the air cleaner housing, slide the air duct off the throttle body and remove the air cleaner housing from the vehicle.
9. Inspect the air duct, air cleaner housing and the intake manifold to make sure the system is dry and clear of any foreign material.
10. Place a shop towel around the spark plugs to catch any fluid that may possibly be under pressure in the cylinder head.
11. Remove the spark plugs. Refer to **SPARK PLUG, REMOVAL** .
12. With the spark plugs removed, rotate the crankshaft using a breaker bar and socket.
13. Identify the fluid in the cylinders (coolant, fuel, oil, etc.).
14. Make sure all fluid has been removed from the cylinders.
15. Repair engine or components as necessary to prevent this problem from occurring again.
16. Squirt a small amount of engine oil into the cylinders to lubricate the walls. This will help prevent engine damage on restart.
17. Install new spark plugs. Refer to **SPARK PLUG, INSTALLATION** .
18. Perform the Engine Oil Service procedure. Refer to **STANDARD PROCEDURE**.
19. Connect negative battery cable.
20. Start the engine and check for leaks.

REPAIR DAMAGED OR WORN THREADS

CAUTION: Always maintain the original center line when drilling and/or tapping holes.

Damaged or worn threads can be repaired. Essentially, this repair consists of:

- Drilling out worn or damaged threads
- Tapping the hole with a special Heli-CoilÂ® Tap or equivalent
- Installing a Heli-CoilÂ® insert into the tapped hole to bring the hole back to its original thread size

REMOVAL

REMOVAL

CAUTION: If the engine encounters a catastrophic failure, the engine oil cooler and lines must be replaced or damage to the new engine and/or components could result.

CAUTION: If the original engine has experienced a catastrophic failure or an individual failure with the piston, cylinder bore, engine block, valve or valve seat, the intake manifold MUST be replaced with a new manifold.

MDS SYSTEM

DESCRIPTION

DESCRIPTION

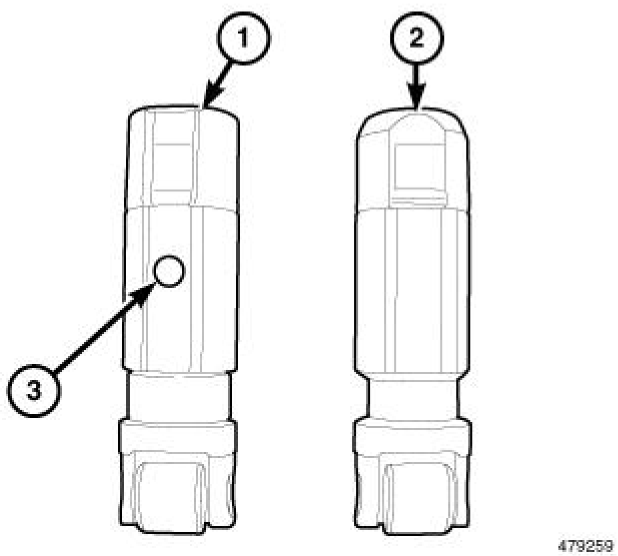

Fig. 53: MDS Lifter
Courtesy of CHRYSLER GROUP, LLC

The Multiple Displacement System (MDS) selectively deactivates cylinders 1, 4, 6 and 7 during steady speed, low acceleration and shallow grade climbing conditions to increase fuel economy.

The MDS can provide a 5 to 20% fuel economy benefit when operating in four-cylinder mode. Depending on driving habits and vehicle usage. For EPA rating purposes the fuel economy is 8 to 15% higher than if the engine was operating on eight-cylinders at all times.

The MDS deactivating lifter (1) can be distinguished from the non-MDS lifter (2) by the disconnecting pin (3) on the side of the MDS lifter.

MDS is integrated into the basic engine architecture requiring these additional components:

- Unique MDS camshaft
- 8 deactivating roller lifters
- 4 MDS control valve solenoids
- MDS control valve solenoid wiring harness
- Oil temperature sensor

OPERATION

OPERATION

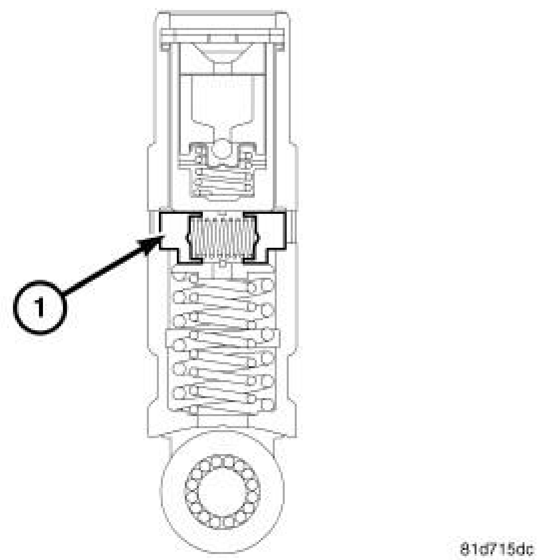

Fig. 54: MDS Lifter Cross-Section
Courtesy of CHRYSLER GROUP, LLC

The Multiple Displacement System (MDS) provides cylinder deactivation during steady speed, low acceleration and shallow grade climbing conditions to increase fuel economy. Both four and eight cylinder configurations have even firing intervals to provide smooth operation. The MDS selectively deactivates cylinders 1, 4, 6, and 7, to improve fuel economy. All deactivated cylinders have unique hydraulic lifters that collapse when deactivated to prevent the valves from opening. Engine oil pressure is used to activate and deactivate the valves. Oil is delivered through special oil passages drilled into the cylinder block. The MDS solenoid valves control the flow. When activated, pressurized oil pushes a latching pin on each MDS lifter which becomes a lost motion link. The base of the MDS lifter follows the camshaft while the top remains stationary. The MDS lifter is held in place against the pushrod by light spring pressure but unable to move because of the much higher force of the valve spring.

NOTE: **It is critical to use the recommended oil viscosity in engines that use MDS.**

Deactivation occurs during the compression stroke of each cylinder, after air and fuel enter the cylinder. Ignition occurs, but the combustion products remain trapped in the cylinder under high pressure, because the valves no longer open. No fuel/air enters or leaves during subsequent piston strokes, this high pressure gas is repeatedly

compressed and expanded like an air spring.

2. Install the air cleaner housing retaining bolt (4) and tighten to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
3. Install the makeup air hose (3) at the air cleaner housing.
4. Connect the intake air temperature sensor electrical connector (2).
5. Position the air duct retaining clamp (1) at the throttle body and tighten to the proper specification. Refer to **TORQUE SPECIFICATIONS**.

CYLINDER HEAD

OPERATION

OPERATION

The cylinder head closes the combustion chamber allowing the pistons to compress the air fuel mixture to the correct ratio for ignition. The valves located in the cylinder head open and close to either allow clean air into the combustion chamber or to allow the exhaust gases out, depending on the stroke of the engine.

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - CYLINDER HEAD GASKET FAILURE

A cylinder head gasket leak can be located between adjacent cylinders or between a cylinder and the adjacent water jacket.

Possible indications of the cylinder head gasket leaking between adjacent cylinders are:

- Loss of engine power
- Engine misfiring
- Poor fuel economy

Possible indications of the cylinder head gasket leaking between a cylinder and an adjacent water jacket are:

- Engine overheating
- Loss of coolant
- Excessive steam (white smoke) emitting from exhaust
- Coolant foaming

CYLINDER-TO-CYLINDER LEAKAGE TEST

To determine if an engine cylinder head gasket is leaking between adjacent cylinders, follow the procedures in Cylinder Compression Pressure Test. Refer to **CYLINDER COMPRESSION PRESSURE LEAKAGE**. An engine cylinder head gasket leaking between adjacent cylinders will result in approximately a 50-70% reduction in compression pressure.

CYLINDER-TO-WATER JACKET LEAKAGE TEST

WARNING: Use extreme caution when the engine is operating with coolant pressure cap removed. Failure to follow this warning may result in serious or fatal injury.

VISUAL TEST METHOD

With the engine cool, remove the coolant pressure cap. Start the engine and allow it to warm up until thermostat opens.

If a large combustion/compression pressure leak exists, bubbles will be visible in the coolant.

COOLING SYSTEM TESTER METHOD

WARNING: With cooling system tester in place, pressure will build up fast. Excessive pressure built up, by continuous engine operation, must be released to a safe pressure level. Never permit pressure to exceed 138 kPa (20 psi). Failure to follow this warning may result in serious or fatal injury.

Install Cooling System Tester (special tool #7700, Tester, Cooling System) or equivalent to pressure cap neck. Start the engine and observe the tester's pressure gauge. If gauge pulsates with every power stroke of a cylinder a combustion pressure leak is evident.

CHEMICAL TEST METHOD

Combustion leaks into the cooling system can also be checked by using Bloc-Chek Kit (special tool #C-3685-A, Bloc-Chek Kit) or equivalent. Perform test following the procedures supplied with the tool kit.

REMOVAL

REMOVAL

1. Remove the intake manifold. Refer to **MANIFOLD, INTAKE, REMOVAL**.
2. Drain the cooling system. Refer to **STANDARD PROCEDURE** .

3. Disconnect the heater hoses (1, 2).
4. Remove the catalytic converters. Refer to **CONVERTER, CATALYTIC, REMOVAL** .
5. Lower the vehicle.
6. If removing the right cylinder head, remove the engine oil dip stick tube retaining nut at the exhaust manifold and remove the oil dip stick tube.
7. Remove the rocker arms and push rods. Refer to **ROCKER ARM, VALVE, REMOVAL**.

11. If necessary, using the sequence shown in illustration, remove the exhaust manifold bolts and remove the manifold.

CLEANING

CLEANING

Clean all surfaces of the cylinder block and cylinder heads.

Clean the cylinder block front and rear gasket surfaces using a suitable solvent.

INSPECTION

INSPECTION

1. Inspect the cylinder head for flatness using a straightedge and a feeler gauge. If tolerances exceed 0.0508 mm (0.002 in.) replace the cylinder head.
2. Inspect the valve seats for damage. Service the valve seats as necessary.
3. Inspect the valve guides for wear, cracks or looseness. If any of these conditions exist, replace the cylinder head.
4. Inspect push rods. Replace worn or bent push rods.

INSTALLATION

INSTALLATION

CAUTION: The cylinder head gaskets (1) are not interchangeable between left and right sides. They are marked "UP" to indicate direction to face up and "L" or "R" to indicate left side or right side of engine block.

3. Clean all sealing surfaces of the engine block and the cylinder head(s) (2).

NOTE: **Rotate crankshaft 45Â° so that all pistons are 1/2 the way down the cylinder bore to avoid piston to valve contact.**

4. Position the **NEW** cylinder head gasket(s) (1) onto the engine block.
5. Position the cylinder head(s) onto the engine block.
6. Install the cylinder head bolts finger tight.

CAUTION: **The 6.4L engine uses a unique 4 layer steel head gasket that must be compressed evenly and completely across the deck surface for proper sealing. The tightening sequence must be followed to ensure all layers are compressed before applying the additional 90 degree turn.**

7. Using the sequence below, tighten the retaining bolts.
   a. Using the sequence shown in illustration, tighten bolts 1-10 to 34 N.m (25 ft. lbs.).
   b. Using the sequence shown in illustration, tighten bolts 11-15 to 20 N.m (15 ft. lbs.).
   c. Using the sequence shown in illustration, tighten bolts 1-10 to 54 N.m (40 ft. lbs.).
   d. Using the sequence shown in illustration, verify bolts 11-15 are 20 N.m (15 ft. lbs.).
   e. Using the sequence shown in illustration, tighten bolts 1-10 to 61 N.m (45 ft. lbs.).
   f. Using the sequence shown in illustration, rotate bolts 1-10 an additional 90 degrees.
   g. Using the sequence shown in illustration, tighten bolts 11-15 to 28 N.m (21 ft. lbs.).
8. Install the push rods and rocker arms. Refer to **ROCKER ARM, VALVE, INSTALLATION**.
9. If removed, install the oil dip stick tube and tighten the retaining nut to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
10. Install the catalytic converters. Refer to **CONVERTER, CATALYTIC, INSTALLATION** .

3. Using the sequence shown in illustration, loosen the rocker shaft assemblies.

CAUTION: The rocker shaft assemblies are not interchangeable between intake and exhaust. The intake rocker arms are marked with an "I".

4. Remove the rocker shaft assemblies. Note the location for reassembly.

CAUTION: The longer pushrods are for the exhaust side, and the shorter pushrods are for intake side.

5. Remove the push rods. Note the push rod location for reassembly.

CAUTION: **The rocker shaft assemblies are not interchangeable between intake and exhaust. The intake rocker arms are marked with the letter "I".**

4. Verify the rocker arms are installed in the correct location.

NOTE:	**Repeat torque sequence several times to ensure rocker shaft assembly is firmly seated.**

5. Using the sequence shown in illustration, tighten the rocker shaft bolts as follows:
   - Snug to 10 N.m (7 ft. lbs.)
   - Torque to 23 N.m (17 ft. lbs.)
   - Individually loosen by 1/2 turn and re-torque to 23 N.m (17 ft. lbs.)
   - Finally, Rotate 30 degrees

11. Install the (special tool #9065C, Compressor, Valve Spring) (2) and the (special tool #9065-3, Adapter, Valve Spring Compressor) (1) and remove the exhaust valve retainer locks.
12. Release the valve spring compressor and remove the valve spring.

NOTE: **The valve springs are interchangeable between intake and exhaust.**

13. Remove and discard the valve guide seal.

INSTALLATION

INSTALLATION

NOTE: **All valve springs and seals are installed in the same manner.**

1. Install a new valve guide seal.

NOTE: **The intake spring retainer has a longer free length compared to the exhaust spring retainer.**

2. Install the valve spring.
3. Install the valve spring retainer.

10. Install the cylinder head cover. Refer to **COVER(S), CYLINDER HEAD, INSTALLATION**.
11. Install the air cleaner body. Refer to **BODY, AIR CLEANER, INSTALLATION**.
12. Connect the negative battery cable.

VALVES, INTAKE AND EXHAUST

DESCRIPTION

VALVES

Both the intake and exhaust valves are made of steel with full chrome plate on valve stems. The intake valve is 54.3 mm (2.14 in.) diameter and the exhaust valve is 42.0 mm (1.65 in.) diameter. All valves use three bead lock keepers and retainers to retain the springs and promote valve rotation.

VALVE GUIDES

The valve guides are made of powdered metal and are pressed into the cylinder head. The guides are not replaceable or serviceable, and valve guide reaming is not recommended. If the guides are worn beyond acceptable limits, replace the cylinder heads.

STANDARD PROCEDURE

STANDARD PROCEDURE - REFACING

NOTE: **Valve seats that are worn or burned can be reworked, provided that the correct angle and seat width are maintained. Otherwise the cylinder head must be replaced.**

NOTE: When refacing valves and valve seats, it is important that the correct size valve guide pilot be used for reseating stones. A true and complete surface must be obtained.

1. Measure the concentricity of the valve seat using a dial indicator. Total runout should not exceed 0.051 mm (0.002 inch.) total indicator reading.
2. Inspect the valve seat with Prussian blue to determine where the valve contacts the seat. To do this, coat the valve seat with Prussian blue then set the valve in place. Rotate the valve using light pressure. If the blue is transferred to the center of the valve face, contact is satisfactory. If the blue is transferred to the top edge of the valve face, lower the valve seat with a 15 degree stone. If the blue is transferred to the bottom edge of the valve face, raise the valve seat with a 65 degree stone.
3. Refer to the VALVE SEAT, VALVE FACE AND SPRING HEIGHT CHART for the proper valve seat width, valve seat angle, valve face angle and valve spring height.

VALVE SEAT, VALVE FACE AND SPRING HEIGHT CHART

DESCRIPTION	SPECIFICATION	
SEAT WIDTH		
INTAKE	0.94 - 1.04 mm	0.037 - 0.041 in.
EXHAUST	1.16 - 1.26 mm	0.046 - 0.050 in.
SEAT ANGLE		
(INT. AND EXT.)	44.5Ā° - 45Ā°	
FACE ANGLE		
INTAKE	45.5Ā° - 46Ā°	
EXHAUST	45Ā° - 45.5Ā°	
SPRING HEIGHT		
INTAKE	52.1 mm	2.051 in.
EXHAUST	51.2 mm	2.016 in.

4. The valve seat must maintain an angle of 44.5Ā° - 45.0Ā°.
5. The valve face must maintain an angle of 45.5Ā° - 46.0Ā° for the Intake and 45.0Ā° - 45.5Ā° for the exhaust.

REMOVAL

REMOVAL

1. Disconnect and isolate the negative battery cable.
2. Remove the cylinder head. Refer to **CYLINDER HEAD, REMOVAL**.
3. Compress the valve springs using the valve spring compressor (special tool #C-3422-D, Compressor, Valve Spring) and adapter (special tool #8464, Adapter, Valve Spring).
4. Remove the valve spring retainer locks, valve spring retainers, valve stem seals and valve springs.
5. Before removing the valves, remove any burrs from the valve spring retainer lock grooves in the valve stems to prevent damage to the valve guides. Identify the valves to ensure installation in their original location.
6. Remove the valves.

INSTALLATION

INSTALLATION

1. Clean the valves thoroughly. Discard burned, warped, and cracked valves.
2. Remove carbon and varnish deposits from inside the valve guides with a reliable guide cleaner.
3. Measure the valve stems for wear. If wear exceeds 0.051 mm (0.002 inch), replace the valve.
4. Coat the valve stems with clean engine oil and insert them into the cylinder head.
5. If the valves or seats have been reground, check valve stem height. If the valve is too long, replace the cylinder head.
6. Install new seals on all valve guides. Install the valve springs and valve spring retainers.

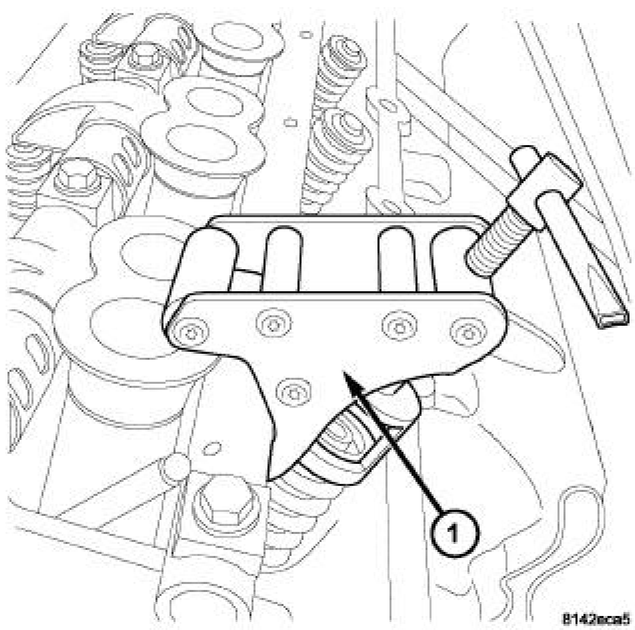

Fig. 96: Exhaust Valve Spring Removal/Installation
Courtesy of CHRYSLER GROUP, LLC

7. Compress the valve springs with the Valve Spring Compressor (special tool #C-3422-D, Compressor, Valve Spring) (1) and Adapter (special tool #8464, Adapter, Valve Spring), install the valve spring retainer locks and release the tool. If the valves and/or seats have been ground, measure the installed height of the springs. Make sure the measurement is taken from the bottom of spring seat in the cylinder head to the bottom surface of valve spring retainer.
8. Install the cylinder head. Refer to **CYLINDER HEAD, INSTALLATION**.
9. Connect the negative battery cable.

ENGINE BLOCK

CLEANING

CLEANING

Thoroughly clean the oil pan and engine block gasket surfaces.

Use compressed air to clean the following:

- Gallery at the oil filter adaptor hole.
- Front and rear oil gallery holes.
- Feed holes for the crankshaft main bearings.

Once the block has been completely cleaned, apply Loctite PST pipe sealant with Teflon 592 to the threads of the front and rear oil gallery plugs. Tighten the 1/4 inch NPT plugs, 3/8 inch NPT plugs and the coolant drain plugs to the proper specification. Refer to **TORQUE SPECIFICATIONS**.

INSPECTION

INSPECTION

ENGINE BLOCK

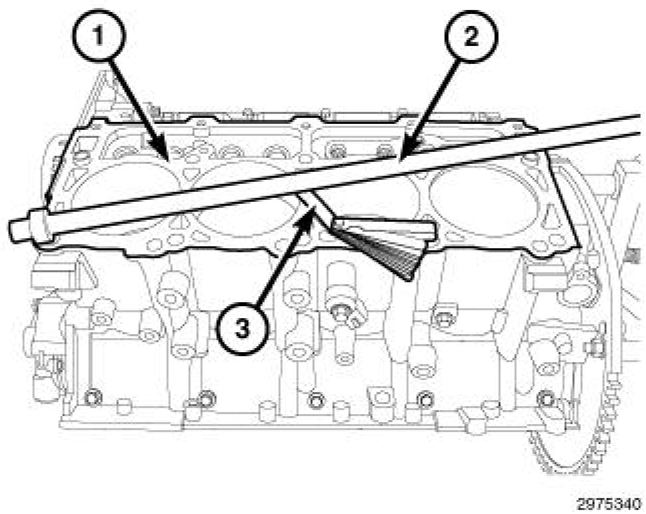

Fig. 97: Checking Engine Block Deck Surface With Precision Straightedge & Feeler Gauge
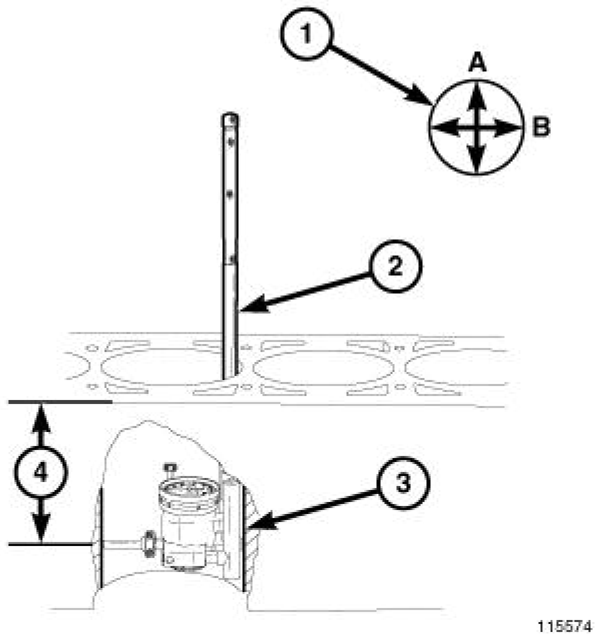
Courtesy of CHRYSLER GROUP, LLC

1. Clean the engine block thoroughly and check all core hole plugs for evidence of leaking and repair if necessary.
2. Examine the engine block and cylinder bores for cracks or fractures.

NOTE:	**Check the engine block deck surface with a precision straightedge and feeler gauge. The surface irregularities should not exceed 0.09 mm (0.0035 in.). Check the deck surface from one end to the other with the precision straightedge positioned across corners and parallel to the block centerline up and down the deck.**

3. Check the engine block deck (1) surfaces for flatness using a precision straightedge (2) and feeler gauge (3).

CYLINDER BORE



[Fig. 98: Measuring Cylinder Bore Diameter]
Courtesy of CHRYSLER GROUP, LLC

1. Use Cylinder Indicator (special tool #C-119, Cylinder Indicator) (2) to correctly measure the inside diameter of the cylinder bore (3). A cylinder bore gauge capable of reading in 0.003 mm (0.0001 in.) increments is required. If a bore gauge is not available, do not use an inside micrometer.
2. Measure the inside diameter of the cylinder bore at three levels below the top of the bore (4). Start at the top of the bore, perpendicular (across or at 90Â°) to the axis of the crankshaft at point A (1).
3. Repeat the measurement near the middle of the bore then repeat the measurement near the bottom of the bore.
4. Determine the taper by subtracting the smaller diameter from the larger diameter.
5. Rotate the measuring device 90Â° to point B (1) and repeat the three measurements. Verify that the maximum taper is within specifications.
6. Determine out-of-roundness by comparing the difference between each measurement.
7. If the cylinder bore taper does not exceed 0.0127 mm (0.0005 inch) and out-of-roundness does not exceed 0.008 mm (0.0003 inch) then the cylinder bore can be honed. If the cylinder bore taper or out- of-round condition exceeds the maximum limits, replace the engine block.

NOTE: **A slight amount of taper always exists in the cylinder bore after the engine has been in use for a period of time.**

MAIN BEARINGS

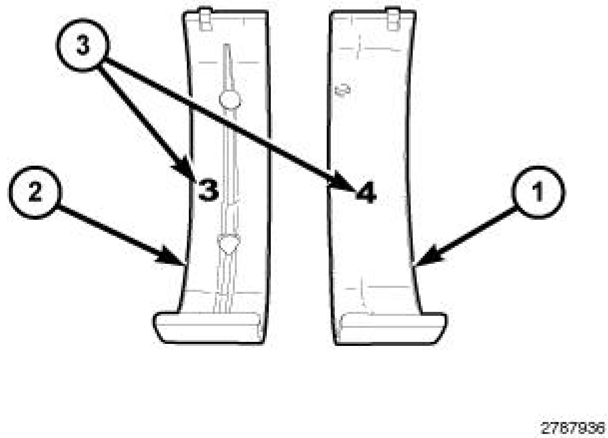


Fig. 99: Main Bearing Inserts
Courtesy of CHRYSLER GROUP, LLC

1. Wipe the main bearing inserts (1, 2) clean.
2. Inspect the inserts for abnormal wear patterns, scoring, grooving, fatigue, pitting and for metal or other foreign material imbedded in the lining.
3. Inspect the back of the inserts for fractures, scrapes or irregular wear patterns.
4. Inspect the insert locking tabs for damage.
5. Inspect the crankshaft thrust washers for scoring, scratches, bluing, discoloration or signs of wear.
6. Replace any bearing that shows abnormal wear.
7. Inspect the main bearing bores for signs of scoring, nicks and burrs.
8. If the engine block main bearing bores show damage, replace the engine block.

BEARING(S), CRANKSHAFT, MAIN

STANDARD PROCEDURE

STANDARD PROCEDURE - CRANKSHAFT MAIN BEARING - FITTING

MAIN BEARING JOURNAL DIAMETER (CRANKSHAFT REMOVED)

CAUTION: If the engine encounters a catastrophic failure, the engine oil cooler and lines must be replaced or damage to the new engine and/or components could result.

Crankshaft removed from the cylinder block.

Clean the oil off the main bearing journal.

Determine the maximum diameter of the journal with a micrometer. Measure at two locations 90Â° apart at each end of the journal.

The maximum allowable taper is 0.008 mm (0.0004 inch). The maximum out-of-round is 0.005 mm (0.0002 inch). Compare the measured diameter with the journal diameter specification (MAIN BEARING SELECTION CHART). Select inserts required to obtain the specified bearing-to-journal clearance.

CRANKSHAFT MAIN BEARING SELECTION

The main bearings are "select fit" to achieve proper oil clearances. For main bearing selection, the crankshaft counterweight has grade identification marks stamped into it. These marks are read from left to right, corresponding with journal number 1, 2, 3, 4 and 5.

NOTE: **Service main bearings are coded. These codes identify what size (color) the bearing is.**

MAIN BEARING SELECTION CHART

GRADE	COLOR	mm	In	FOR USE WITH JOURNAL SIZE
-	**LOWER**	-	-	64.988-64.995 mm
A	**ORANGE**	0.008 mm U/S	(0.0004 in.) U/S	(2.5585- 2.5588 in.)
-	**LOWER**	-	-	64.996-65.004 mm
B	**BLACK**	NOMINAL	NOMINAL	(2.5588-2.5592 in.)
-	**LOWER**	-	-	65.005-65.012 mm
C	**GREEN**	0.008 mm O/S	(0.0004 in.) O/S	(2.5592-2.5595 in.)

INSPECTION

INSPECTION

CAUTION: **If the engine encounters a catastrophic failure, the engine oil cooler and lines must be replaced or damage to the new engine and/or components could result.**

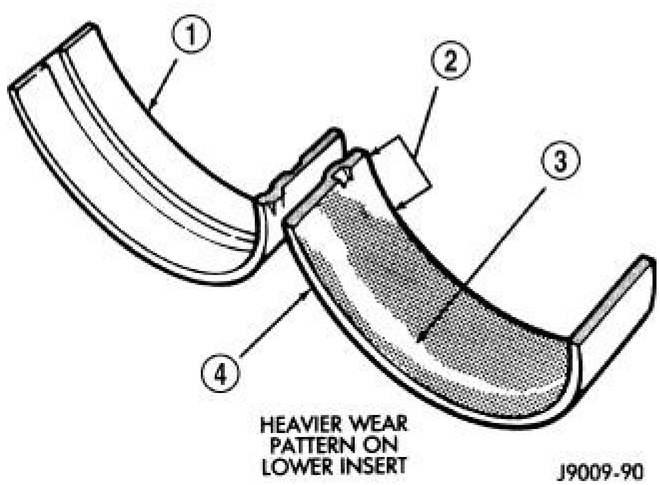

Fig. 100: Main Bearing Wear Patterns
Courtesy of CHRYSLER GROUP, LLC

Wipe the inserts clean and inspect for abnormal wear patterns and for metal or other foreign material imbedded in the lining. Normal main bearing insert wear patterns are illustrated.

NOTE: **If any of the crankshaft journals are scored, the crankshaft must be repaired or replaced.**

Inspect the back of the inserts for fractures, scoring or irregular wear patterns.

Inspect the upper insert locking tabs for damage.

Replace all damaged or worn bearing inserts.

CAMSHAFT, ENGINE

REMOVAL

CAMSHAFT CORE HOLE PLUG

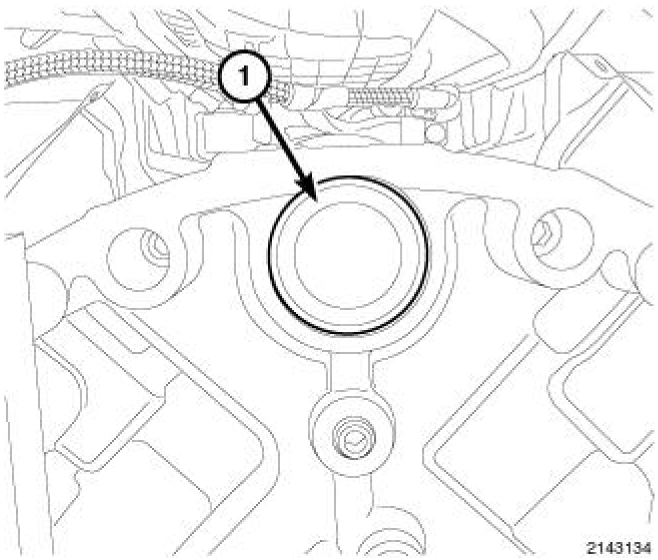

Fig. 101: Camshaft Core Hole Plug
Courtesy of CHRYSLER GROUP, LLC

1. Perform the fuel system pressure release procedure. Refer to **FUEL DELIVERY, GAS, STANDARD PROCEDURE** .
2. Remove the engine from the vehicle. Refer to **REMOVAL**.
3. On automatic transmission models, remove the flexplate. Refer to **FLEXPLATE, REMOVAL**.
4. On manual transmission models, remove the flywheel. Refer to **FLYWHEEL, REMOVAL** .

CAUTION: Do not damage the rear surface of the camshaft or the core plug sealing surface, when removing the core plug.

5. Using a suitable sharp punch, punch a small hole in the camshaft core hole plug (1).
6. Insert a short sheet metal screw into the small hole in the camshaft core hole plug.
7. Using a suitable slide hammer puller, remove the rear camshaft core hole plug.

CAMSHAFT

1. Remove both cylinder heads. Refer to **CYLINDER HEAD, REMOVAL**.

CAUTION: The 6.4L Multi Displacement System (MDS) engine uses both standard roller lifters and deactivating roller lifters. The deactivating roller lifters must be used in cylinders 1, 4, 6, 7. The deactivating lifters can be

identified by the two holes in the side of the lifter body, for the latching pins.

CAUTION: Whenever the camshaft is replaced, all lifters must be replaced. If the lifter and retainer assemblies are to be reused, identify the lifters to ensure installation in their original location or engine damage could result.

CAUTION: The lifter and retainer assembly must be installed as a unit.

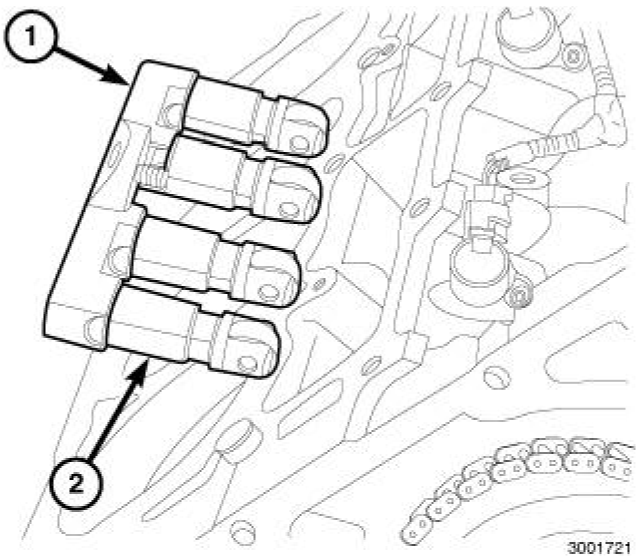

Fig. 102: Identifying Lifters & Retainers

2. Remove the lifters (2) and retainer (1) as an assembly. Refer to **LIFTER(S), HYDRAULIC, ROLLER, REMOVAL**.
3. Remove the radiator. Refer to **RADIATOR, ENGINE COOLING, REMOVAL** .
4. Remove the A/C condenser. Refer to **CONDENSER, A/C, REMOVAL** .
5. Remove the timing chain and camshaft phaser. Refer to **CHAIN AND SPROCKETS, TIMING, REMOVAL**.

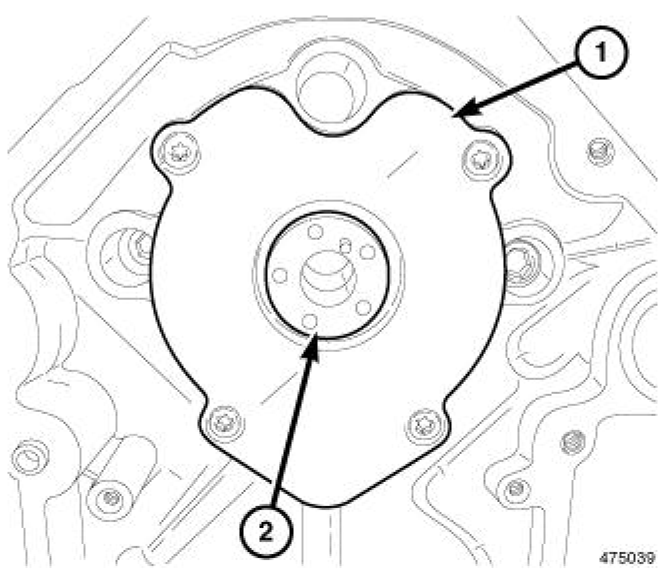

Fig. 103: Camshaft Thrust Plate

7. Install a long bolt (2) into the front of the camshaft to aid in removal.
8. Remove the camshaft using care not to damage the camshaft bearings with the camshaft lobes (1).

INSPECTION

INSPECTION

NOTE: **The cam bearings are not serviceable. Do not attempt to replace cam bearings for any reason.**

INSTALLATION

CAMSHAFT CORE HOLE PLUG

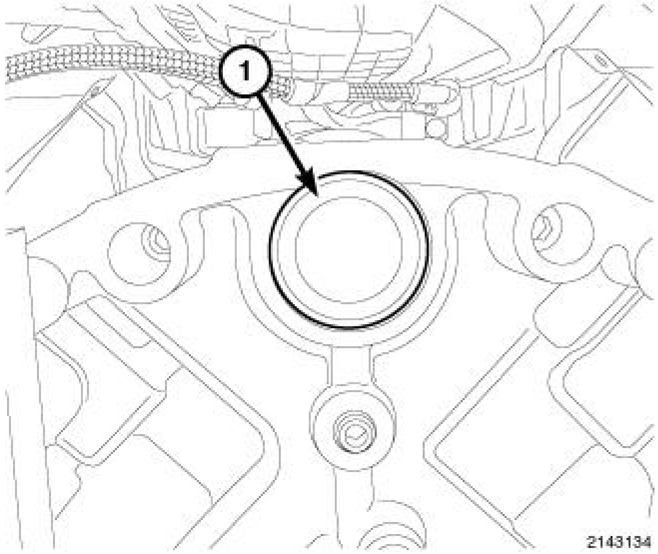

Fig. 105: Camshaft Core Hole Plug
Courtesy of CHRYSLER GROUP, LLC

1. Clean the core hole in the cylinder block.

NOTE: **Do not apply adhesive to the new camshaft core hole plug. A new plug has adhesive pre-applied.**

2. Install a new camshaft core hole plug (1) located at the rear of cylinder block, using a suitable flat faced tool. The plug must be fully seated on the cylinder block shoulder.
3. On manual transmission models, install the flywheel. Refer to **FLYWHEEL, INSTALLATION** .
4. On automatic transmission models, install the flexplate. Refer to **FLEXPLATE, INSTALLATION**.
5. Install the engine. Refer to **INSTALLATION**.

CAMSHAFT

CAUTION: **The 6.4L engine uses a unique camshaft for use with the Multi Displacement System (MDS). When installing a new camshaft, the replacement camshaft must be compatible with MDS.**

CAUTION: **Use care when installing the camshaft into the engine block, do not damage the camshaft bearings with the camshaft lobes.**

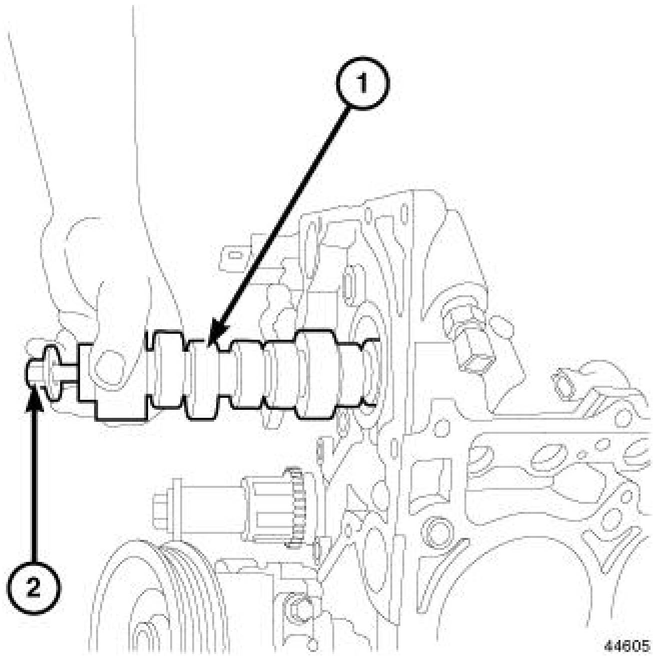

Fig. 106: Removing/Installing Camshaft
Courtesy of CHRYSLER GROUP, LLC

1. Lubricate the camshaft lobes (1) and the camshaft bearing journals with clean engine oil.
2. Install a long bolt (2) into the front of the camshaft to aid in the installation, carefully install the camshaft into the engine block.

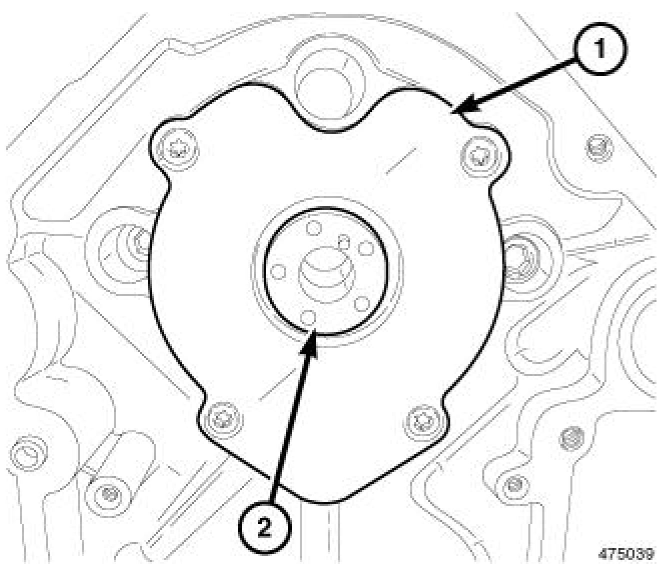

Fig. 107: Camshaft Thrust Plate
Courtesy of CHRYSLER GROUP, LLC

3. Install the camshaft thrust plate (1) and tighten retaining bolts to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
4. Using a suitable dial indicator, measure the camshaft end play. Refer to **ENGINE SPECIFICATIONS**. If not within specification, install a new thrust plate.
5. Install the timing chain and camshaft phaser. Refer to **CHAIN AND SPROCKETS, TIMING, INSTALLATION**.

6. Install the A/C condenser. Refer to **CONDENSER, A/C, INSTALLATION** .
7. Install the radiator. Refer to **RADIATOR, ENGINE COOLING, INSTALLATION** .

CAUTION: **The 6.4L Multi Displacement System (MDS) engine uses both standard roller lifters and deactivating roller lifters. The deactivating roller lifters must be used in cylinders 1, 4, 6, 7. The deactivating lifters can be identified by the two holes in the side of the lifter body, for the latching pins.**

CAUTION: **Whenever the camshaft is replaced, all lifters must be replaced. If the lifter and retainer assemblies are to be reused, identify the lifters to ensure installation in their original location or engine damage could result.**

CAUTION: **The lifter and retainer assembly must be installed as a unit.**

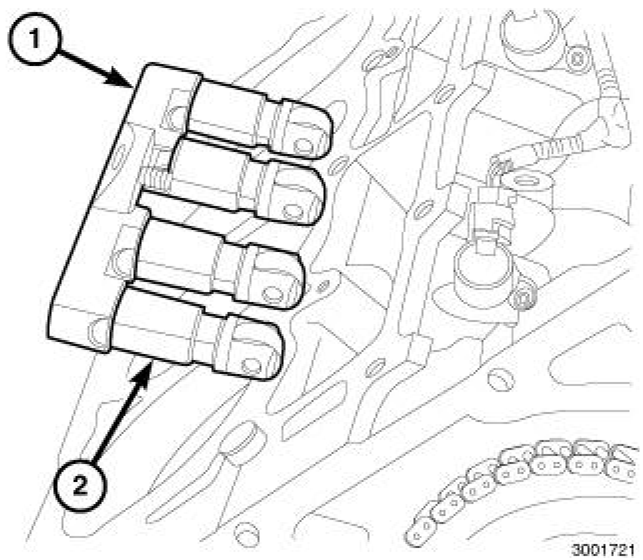

Fig. 108: Identifying Lifters & Retainers
Courtesy of CHRYSLER GROUP, LLC

8. Install the lifters (2) and retainer (1) as an assembly into their original location. Refer to **LIFTER(S), HYDRAULIC, ROLLER, INSTALLATION**.
9. Install both cylinder heads. Refer to **CYLINDER HEAD, INSTALLATION**.

NOTE: **The Cam/Crank Variation Relearn procedure must be performed using the scan tool anytime there has been a repair/replacement made to a powertrain system. For example: flywheel, valvetrain, camshaft and/or crankshaft sensors or components.**

CRANKSHAFT

REMOVAL

REMOVAL

CAUTION: **If the engine encounters a catastrophic failure, the engine oil cooler and lines**

must be replaced or damage to the new engine and/or components could result.

1. Remove the engine. Refer to **REMOVAL**.
2. Secure the engine onto a suitable engine stand.
3. Remove the crankshaft rear oil seal retainer. Refer to **RETAINER, CRANKSHAFT REAR OIL SEAL, REMOVAL**.
4. Remove the oil pan and the oil pump pickup tube. Refer to **PAN, OIL, REMOVAL**.
5. Remove the timing chain, camshaft phaser and crankshaft sprocket. Refer to **CHAIN AND SPROCKETS, TIMING, REMOVAL**.

CAUTION: Do not use a number stamp or a punch to mark connecting rods or caps, as damage to connecting rods could occur.

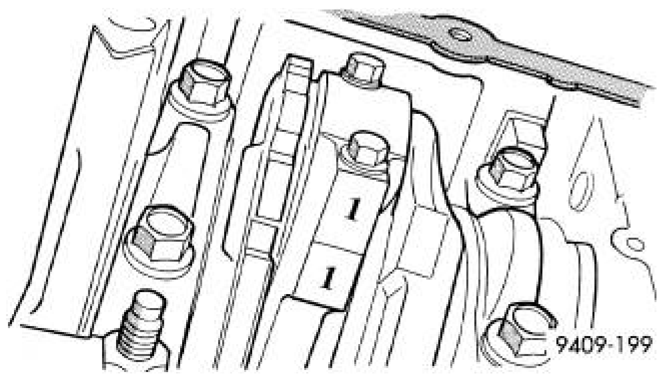

Fig. 109: Identifying Mark On Connecting Rod And Bearing Cap

NOTE: Connecting rods and bearing caps are not interchangeable and should be marked before removal to ensure correct reassembly.

6. Mark the connecting rod and bearing cap location using a permanent ink marker or scribe tool.
7. Remove the rod bearing caps and bearings.

CAUTION: Do not use a number stamp or a punch to mark main bearing caps as damage to bearing caps and/or bearings could occur.

NOTE: Main bearing caps are not interchangeable and should be marked before removal to ensure correct reassembly.

8. Mark the main bearing caps using a permanent ink marker or scribe tool.

NOTE: **The main bearing cap cross-bolts are torqued after the final torque of the main cap bolts.**

12. Install the cross-bolts finger tight.
13. Using the sequence shown in illustration, tighten the cross-bolts to 34 N.m (25 ft. lbs.).
14. Again, using the sequence shown in illustration, repeat the cross-bolt tightening procedure using the same torque.
15. Measure the crankshaft end play. Refer to **STANDARD PROCEDURE**.

CAUTION: **The connecting rod bolts must not be reused. Always replace the connecting rod bolts whenever they are loosened or removed.**

20. If required, measure the connecting rod side clearance (1, 2). Refer to **ENGINE SPECIFICATIONS**.
21. Install the timing chain, camshaft phaser and crankshaft sprocket. Refer to **CHAIN AND SPROCKETS, TIMING, INSTALLATION**.
22. Install the crankshaft rear oil seal retainer. Refer to **RETAINER, CRANKSHAFT REAR OIL SEAL, INSTALLATION**.
23. Install the oil pump pickup tube and oil pan. Refer to **PAN, OIL, INSTALLATION**.
24. Install the engine. Refer to **INSTALLATION**.
25. Start the engine and check for leaks.

NOTE: **The Cam/Crank Variation Relearn procedure must be performed using the scan tool anytime there has been a repair/replacement made to a powertrain system. For example: flywheel, valvetrain, camshaft and/or crankshaft sensors or components.**

DAMPER, VIBRATION

DESCRIPTION

DESCRIPTION

The crankshaft damper is used to control the resonance that is produced by the engine. The Noise, Vibration, and Harshness (NVH) created from the crankshaft can be controlled by dissipating the torque energy through the damper.

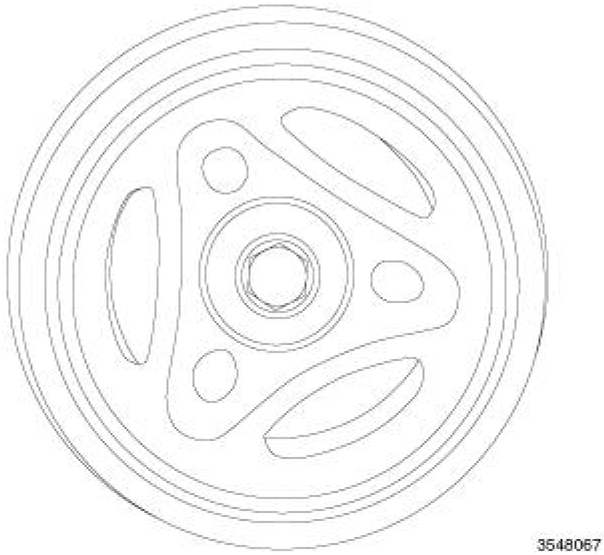

Fig. 121: Crankshaft Damper & Harden Steel Bolt
Courtesy of CHRYSLER GROUP, LLC

The crankshaft damper is held to the crankshaft by means of a harden steel bolt. The damper is pressed onto a specific machined surface of the crankshaft.

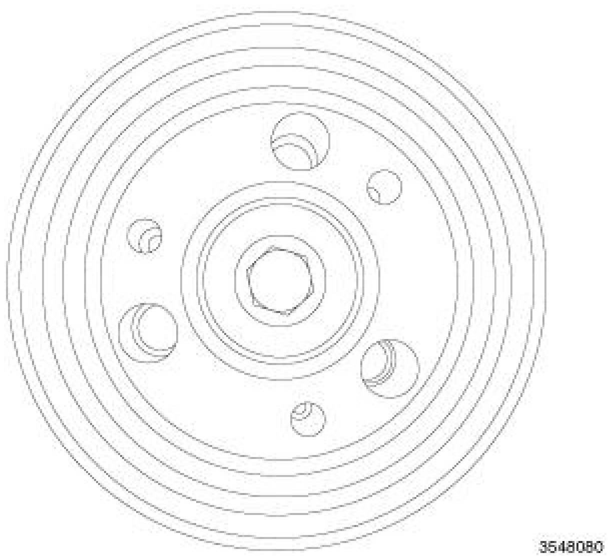

Fig. 122: HEMIÃ® Engine Crankshaft Damper
Courtesy of CHRYSLER GROUP, LLC

The HEMIÃ® Engines incorporate various crankshaft vibration dampers depending on the engine application.

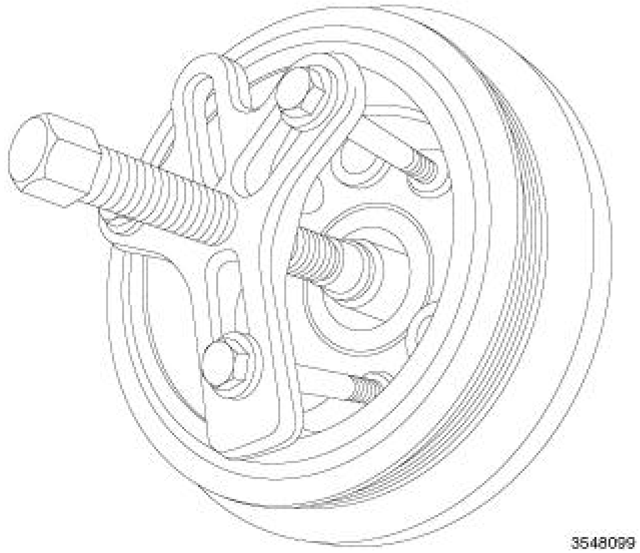

Fig. 123: Removing Vibration Damper
Courtesy of CHRYSLER GROUP, LLC

Finding the proper puller for the application will ensure no damage will come to the damper. The flange puller is used by installing 3 bolts into the pre-tapped holes in the damper.

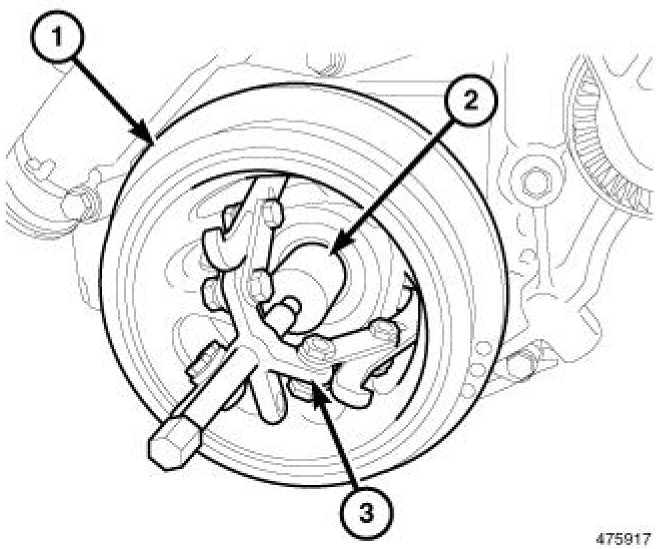

Fig. 124: Removing Vibration Damper

Some pulleys that do not have bolt holes can be removed with a three jaw style (special tool #1023, Puller).

REMOVAL

REMOVAL

1. Disconnect the negative battery cable.
2. Drain the cooling system. Refer to **STANDARD PROCEDURE** .

LIFTER(S), HYDRAULIC, ROLLER

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - HYDRAULIC ROLLER LIFTERS

Before disassembling any part of the engine to correct lifter noise, check the oil pressure. If the vehicle has no oil pressure gauge, install a reliable gauge at the pressure sending-unit. The pressure should be between 207-552 kPa (30-70 psi) at 3, 000 RPM.

Check the oil level after the engine reaches normal operating temperature. Allow 5 minutes to stabilize oil level, check dipstick. The oil level in the pan should never be above the FULL mark or below the ADD OIL mark on the dipstick. Either of these two conditions could be responsible for noisy lifters.

OIL LEVEL

HIGH

If oil level is above the FULL mark, it is possible for the connecting rods to dip into the oil. With the engine running, this condition could create foam in the oil pan. Foam in oil pan would be fed to the hydraulic lifters by the oil pump causing them to lose length and allow valves to seat noisily.

LOW

Low oil level may allow oil pump to take in air. When air is fed to the lifters, they lose length, which allows valves to seat noisily. Any leaks on intake side of oil pump through which air can be drawn will create the same lifter action. Check the lubrication system from the intake strainer to the pump cover, including the relief valve retainer cap. When lifter noise is due to aeration, it may be intermittent or constant, and usually more than one lifter will be noisy. When oil level and leaks have been corrected, operate the engine at fast idle. Run engine for a sufficient time to allow all of the air inside the lifters to be bled out.

LIFTER NOISE DIAGNOSIS

1. To determine source of lifter noise, crank the engine with cylinder head covers removed.
2. Feel each valve spring or rocker arm to detect noisy lifter. The noisy lifter will cause the affected spring and/or rocker arm to vibrate or feel rough in operation.

NOTE: **Worn valve guides or cocked springs are sometimes mistaken for noisy lifters. If such is the case, noise may be dampened by applying side thrust on the valve spring. If noise is not noticeably reduced, it can be assumed the noise is in the lifter. Inspect the rocker arm push rod sockets and push rod ends for wear.**

3. Valve lifter noise ranges from light noise to a heavy click. A light noise is usually caused by excessive leak-down around the unit plunger or by the plunger partially sticking in the lifter body cylinder. The lifter should be replaced. A heavy click is caused by a lifter check valve not seating or by foreign particles wedged between the plunger and the lifter body. This will cause the plunger to stick in the down position. This heavy click will be accompanied by excessive clearance between the valve stem and rocker arm as the valve closes. In either case, lifter assembly should be removed for inspection and cleaning.
4. The valve train generates a noise very much like a light lifter noise during normal operation. Care must be taken to ensure that lifters are making the noise. If more than one lifter seems to be noisy, it's probably not the lifters.

REMOVAL

REMOVAL

1. Disconnect and isolate the negative battery cable.
2. Remove the cylinder head. Refer to **CYLINDER HEAD, REMOVAL**.

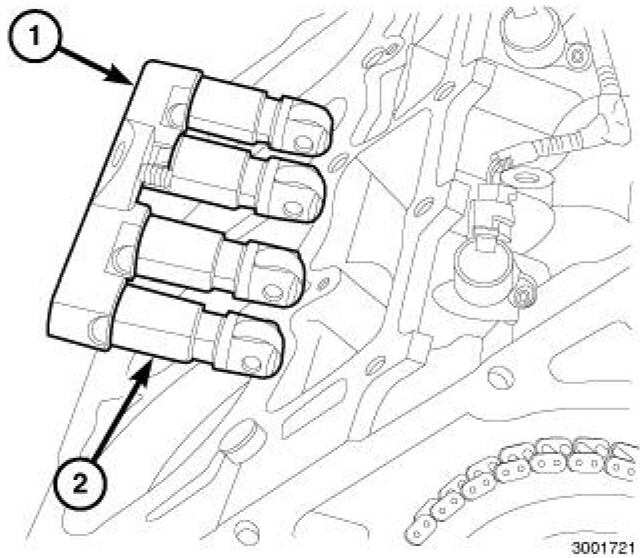

Fig. 133: Identifying Lifters & Retainers
Courtesy of CHRYSLER GROUP, LLC

CAUTION: If the lifter and retainer assembly are to be reused, identify the lifters to ensure installation in their original location or engine damage could result.

CAUTION: The lifter and retainer assembly must be installed as a unit.

3. Remove the lifters (2) and retainer (1) as an assembly.
4. Check the camshaft lobes for abnormal wear.

INSTALLATION

INSTALLATION

CAUTION: If the lifter and retainer assembly are to be reused, identify the lifters to ensure installation in their original location or engine damage could result.

CAUTION: The lifter and retainer must be installed as an assembly.

2. Install the lifters (2) and retainer (1) as an assembly into their original location.
3. Tighten the lifter retainer bolt (1) to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
4. Install the cylinder head. Refer to **CYLINDER HEAD, INSTALLATION**.
5. Connect the negative battery cable.

CAUTION: To prevent damage to valve assemblies, do not run the engine above fast idle until all hydraulic lifters have filled with oil and have become quiet.

RETAINER, CRANKSHAFT REAR OIL SEAL

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - REAR SEAL AREA LEAKS

The crankshaft rear oil seal is integral to the crankshaft rear oil seal retainer and is serviced as an assembly.

Since it is sometimes difficult to determine the source of an oil leak in the rear seal area of the engine, a more involved inspection is necessary. The following steps should be followed to help pinpoint the source of the leak.

If the leakage occurs at the crankshaft rear oil seal area:

1. Raise and support the vehicle.
2. Remove the transmission inspection/torque converter access cover.
3. Inspect the rear of the cylinder block for evidence of oil leakage and note the following:
    - Circular spray pattern generally indicates seal leakage or crankshaft damage.

- Where leakage tends to run straight down, possible causes are a porous block, camshaft bore cup plugs, oil gallery pipe plugs, oil filter runoff and main bearing cap to cylinder block mating surfaces. See appropriate Engine component for proper repair procedures of these items.

4. If no leaks are detected, pressurize the crankcase as outlined in the **AIR LEAK DETECTION TEST METHOD**.

CAUTION: Do not exceed 20.6 kPa (3 psi).

5. If the leak is not detected, very slowly turn the crankshaft and watch for leakage. If a leak is detected between the crankshaft and seal while slowly turning the crankshaft, it is possible the crankshaft seal surface is damaged. The seal area on the crankshaft could have minor nicks or scratches that can be polished out using an emery cloth.

CAUTION: Use extreme caution when crankshaft polishing is necessary to remove minor nicks or scratches. The crankshaft seal flange is specially machined to complement the function of the rear oil seal.

6. For bubbles that remain steady with shaft rotation, no further inspection can be done. Refer to **RETAINER, CRANKSHAFT REAR OIL SEAL, REMOVAL**.

REMOVAL

REMOVAL

NOTE: The crankshaft rear oil seal is integral to the crankshaft rear oil seal retainer and must be replaced as an assembly.

NOTE: The crankshaft rear oil seal retainer can not be reused after removal.

NOTE: This procedure can be performed in vehicle.

1. Disconnect the negative battery cable.
2. Remove the flexplate or flywheel. Refer to **FLEXPLATE, REMOVAL**.
3. Remove the oil pan. Refer to **PAN, OIL, REMOVAL**.

4. Using the sequence shown in illustration, remove the rear oil seal retainer mounting bolts.
5. Remove and discard the rear oil seal retainer.

INSTALLATION

INSTALLATION

NOTE: **The crankshaft rear oil seal is integral to the crankshaft rear oil seal retainer and must be replaced as an assembly.**

NOTE: **The crankshaft rear oil seal retainer can not be reused after removal.**

1. Thoroughly clean all gasket residue from the engine block.
2. Position the gasket onto the new crankshaft rear oil seal retainer.
3. Position the crankshaft rear oil seal retainer onto the engine block.

4. Using the sequence shown in illustration, install the crankshaft rear oil seal retainer mounting bolts and tighten to the proper specification. Refer to **ENGINE SPECIFICATIONS**.
5. Install the oil pan. Refer to **PAN, OIL, INSTALLATION**.
6. Install the flexplate or flywheel. Refer to **FLEXPLATE, INSTALLATION**.
7. Install a NEW oil filter and fill the crankcase with the specified type and amount of engine oil. Refer to **STANDARD PROCEDURE**.
8. Connect the negative battery cable.
9. Start the engine and check for leaks.

RING(S), PISTON

STANDARD PROCEDURE

STANDARD PROCEDURE

PISTON RING FITTING

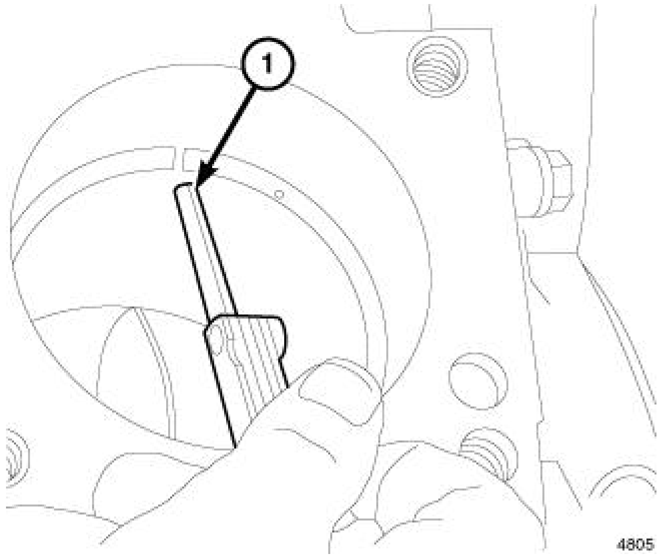

Fig. 138: Using Feeler Gauge To Check Ring End Gap
Courtesy of CHRYSLER GROUP, LLC

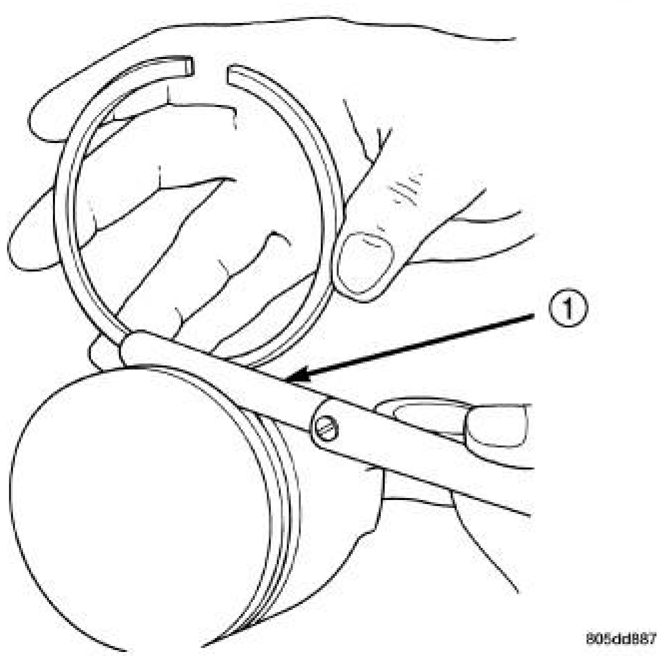
CAUTION: Before reinstalling used piston rings or installing new piston rings, the piston ring clearances must be checked or engine damage may result.

1. Wipe the cylinder bore clean.
2. Insert the piston ring into the cylinder bore.

NOTE: The piston ring gap measurement must be made with the piston ring positioned at least 12 mm (0.50 inch) from bottom of cylinder bore.

3. Using a piston, make sure that the piston ring is squared in the cylinder bore. Slide the piston ring downward into the cylinder.
4. Using a feeler gauge (1), check the piston ring end gap, replace any rings not within specification.

PISTON RING SIDE CLEARANCE



[Fig. 139: Measuring Piston Ring Side Clearance](#)
Courtesy of CHRYSLER GROUP, LLC

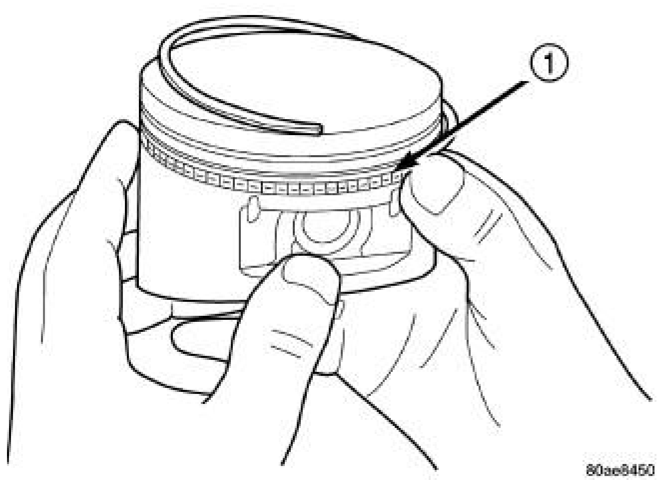
NOTE: Make sure the piston ring grooves are clean and free of nicks and burrs.

1. Measure the piston ring side clearance with a feeler gauge (1) as shown in illustration. Make sure the feeler gauge fits snugly between the piston ring land and the piston ring, replace any ring not within specification.

   NOTE: Make sure the marks on the compression rings face upward.

2. Rotate the ring around the piston. The ring must rotate in the groove with out binding.

PISTON RING INSTALLATION



[Fig. 140: Installing Piston Ring Side Rail](#)
Courtesy of CHRYSLER GROUP, LLC

1. Install the oil ring expander.
2. Install the lower side rail by placing one end between the piston ring groove and the expander ring (1). Hold the lower side rail end firmly and press down the portion to be installed until the side rail is in position. Repeat this step for the upper side rail.

5. Install the oil ring expander gap at the (5) position.
6. Install the oil ring lower side rail gap at the (4) position.
7. Install the oil ring upper side rail gap at the (1) position.
8. Install the second compression ring gap at the (5) position.
9. Install the top compression ring gap at the (2) position.

ROD, PISTON AND CONNECTING

DESCRIPTION

DESCRIPTION

CAUTION: Do not use a metal stamp to mark connecting rods as damage may result, instead use ink or a scratch awl.

The pistons are made of a high-strength aluminum alloy. Piston skirts are coated with a solid lubricant (Molykote) to reduce friction and provide scuff resistance. The piston top ring groove and land is anodized. The connecting rods are made of forged powdered metal with a "fractured cap" design. A floating piston pin is used to attach the piston and connecting rod.

STANDARD PROCEDURE

STANDARD PROCEDURE - PISTON FITTING

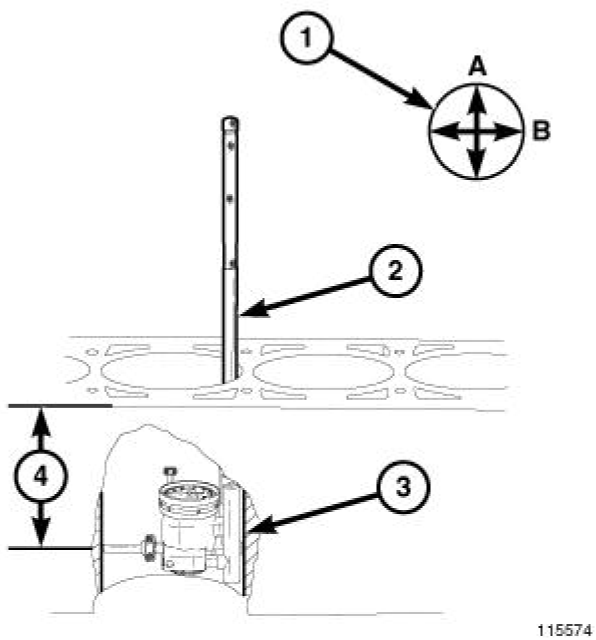

Fig. 143: Measuring Cylinder Bore Diameter
Courtesy of CHRYSLER GROUP, LLC

1. Use Cylinder Indicator (special tool #C-119, Cylinder Indicator) (2) to correctly measure the inside diameter of the cylinder bore (3). A cylinder indicator capable of reading in 0.003 mm (0.0001 in.) increments is required. If a cylinder indicator is not available, do not use an inside micrometer.
2. Measure the inside diameter of the cylinder bore at a point 38.0 mm (1.5 inches) below top of bore (4). Start perpendicular (across or at 90Â°) to the axis of the crankshaft at point A and then take an additional bore reading 90Â° to that at point B.

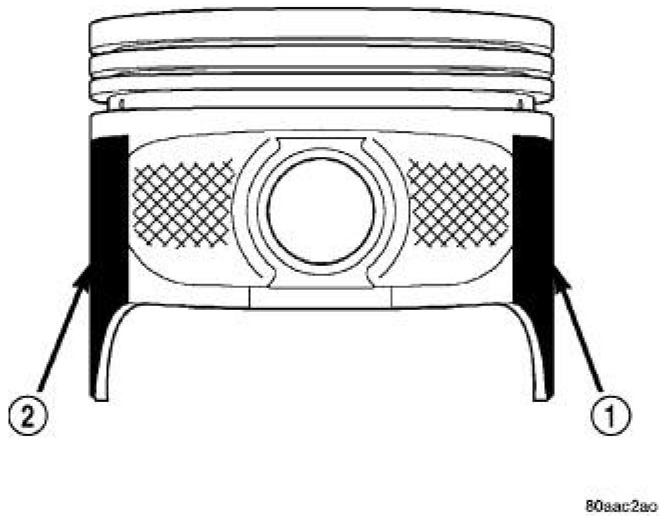

Fig. 144: Moly Coated Piston
Courtesy of CHRYSLER GROUP, LLC

NOTE: The coated pistons, piston pins and connecting rods are pre-assembled and serviced as an assembly.

3. The piston and rod assembly is specific for the left cylinder bank (odd numbered) and the right cylinder bank (even numbered) and must not be interchanged.
4. The coating material (1, 2) is applied to the piston after the final piston machining process. Measuring the outside diameter of a coated piston will not provide accurate results. Therefore measuring the inside diameter of the cylinder bore with a cylinder indicator is **MANDATORY** . To correctly select the proper size piston, a cylinder indicator capable of reading in 0.003 mm (0.0001 in.) increments is required.
5. Piston installation into the cylinder bore requires slightly more pressure than that required for non-coated pistons. The bonded coating on the piston will give the appearance of a line-to-line fit with the cylinder bore.

REMOVAL

REMOVAL

CAUTION: If the engine encounters a catastrophic failure, the engine oil cooler and lines must be replaced or damage to the new engine and/or components could result.

1. Remove the cylinder head(s). Refer to **CYLINDER HEAD, REMOVAL**.
2. Remove the oil pan. Refer to **PAN, OIL, REMOVAL**.
3. If necessary, remove the ridge on top of the cylinder bores with a reliable ridge reamer before removing pistons from engine block. **Be sure to keep the tops of the pistons covered during this operation.**

CAUTION: When removing and installing the pistons and connecting rods, do not damage the piston oil cooler jets. If the jets are bent, engine damage may occur.

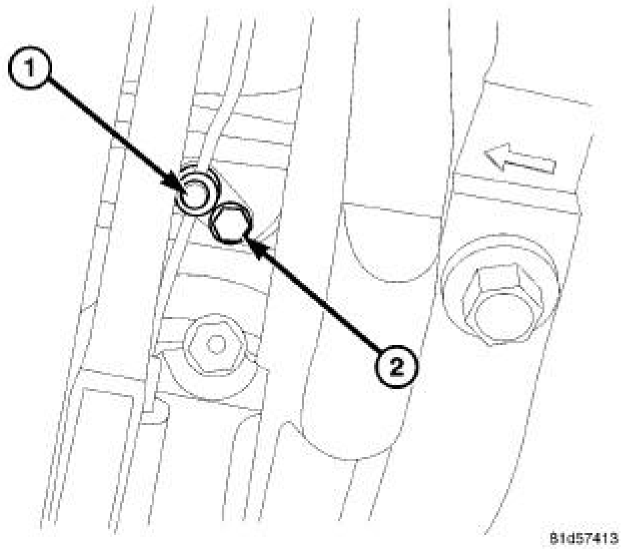

Fig. 145: Piston Oil Jet & Bolt
Courtesy of CHRYSLER GROUP, LLC

4. Remove the piston oil cooler jet(s) retaining bolt(s) (2) and remove the piston oil cooler jet(s) (1).

CAUTION: **Do not use a number stamp or a punch to mark connecting rods or caps, as damage to connecting rods could occur.**

CAUTION: **Care must be taken not to damage the fractured rod and cap joint face surfaces as engine damage may occur.**

CAUTION: **Care must be taken not to nick crankshaft journals as engine damage may occur.**

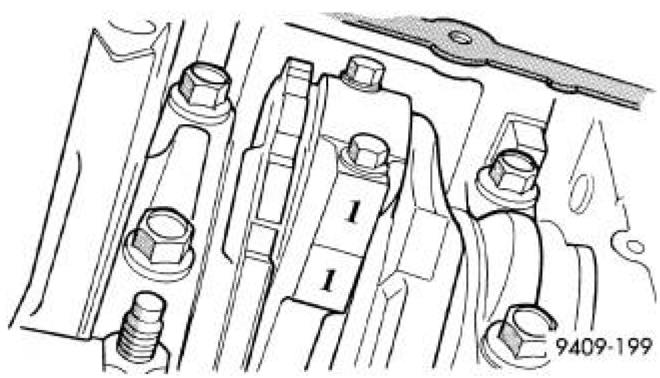

Fig. 146: Identifying Mark On Connecting Rod And Bearing Cap
Courtesy of CHRYSLER GROUP, LLC

NOTE: **Connecting rods and bearing caps are not interchangeable and should be marked before removing to ensure correct reassembly.**

5. Mark the connecting rod and bearing cap position using a permanent ink marker or scribe tool.

NOTE: **Pistons and connecting rod assemblies must be removed from the top of the engine block. When removing the piston and connecting rod assemblies from the engine, rotate the crankshaft so each connecting rod is centered in the cylinder bore.**

6. Remove the connecting rod cap and carefully remove the piston from the cylinder bore, repeat this procedure for each piston being removed.
7. Immediately after removing the piston and connecting rod, install the bearing cap on the mating connecting rod to prevent damage to the fractured cap and rod surfaces.
8. Carefully remove the piston rings from the piston(s), starting from the top ring down.

CLEANING

CLEANING

CAUTION: **DO NOT use a wire wheel or other abrasive cleaning devise to clean the pistons or connecting rods. The pistons have a Moly coating, this coating must not be damaged.**

1. Using a suitable cleaning solvent clean the pistons in warm water and towel dry.
2. Use a wood or plastic scraper to clean the ring land grooves.

INSPECTION

INSPECTION

Check the connecting rod journal for excessive wear, taper and scoring.

Check the connecting rod for signs of twist or bending.

Check the piston for taper and elliptical shape before it is fitted into the cylinder bore. Refer to **STANDARD PROCEDURE**.

Check the piston for scoring, or scraping marks on the piston skirts. Check the ring lands for cracks and/or deterioration.

INSTALLATION

INSTALLATION

CAUTION: **If the engine encounters a catastrophic failure, the engine oil cooler and lines must be replaced or damage to the new engine and/or components could result.**

NOTE: **Before reinstalling used rings or installing new rings, the ring clearances must be checked.**

NOTE: **Make sure the piston ring grooves are clean and free of nicks and burrs.**

1. Check piston ring clearance. Refer to **STANDARD PROCEDURE**.
2. Before installing piston and connecting rod assemblies into the bore, install the piston rings. Refer to **STANDARD PROCEDURE**.

3. Immerse the piston head and rings in clean engine oil and position a ring compressor over the piston and rings and tighten the ring compressor. **Make sure the position of rings do not change during this operation.**

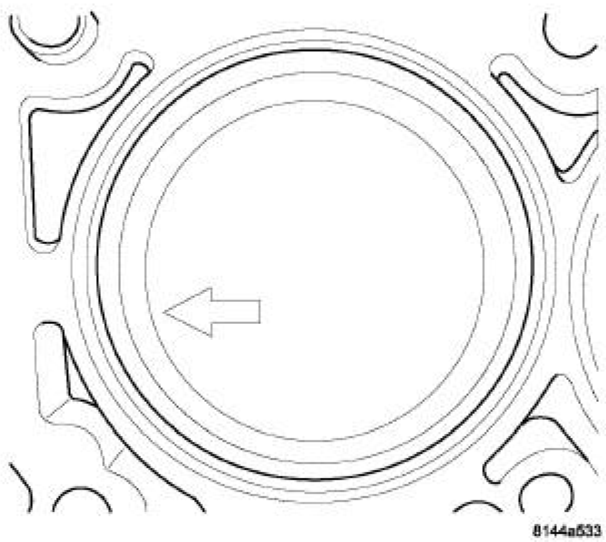

Fig. 147: Piston Direction Arrow
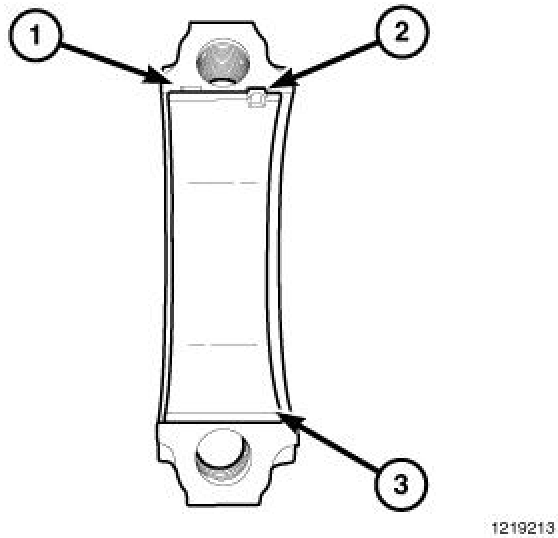
Courtesy of CHRYSLER GROUP, LLC

4. The pistons are marked on the piston pin bore surface with an raised "F" or arrow on top of piston indicating installation position. This mark must be pointing toward the front of the engine on both cylinder banks.
5. Wipe the cylinder bore clean and lubricate with clean engine oil.
6. Rotate the crankshaft until the connecting rod journal is centered with the cylinder bore.
7. Insert the piston and rod assembly into the cylinder bore and carefully position the connecting rod over the crankshaft journal.
8. Tap the piston down in cylinder bore using a hammer handle. While at the same time, guide the connecting rod into position on crankshaft rod journal.
9. Perform the measure bearing clearance procedure. Refer to **ENGINE BLOCK, STANDARD PROCEDURE** .



[**Fig. 148: Connecting Rod Cap**]

10. Wipe the connecting rod cap (1) clean and lubricate with clean engine oil and install the bearing (3).

NOTE: **The connecting rods and bearing caps are not interchangeable, line up the previously marked bearing caps and connecting rods to ensure assembly to their original location.**

11. Lubricate the bearing surfaces with clean engine oil and position the rod cap onto the connecting rod.

CAUTION: **When installing the connecting rods, make sure the wide side of the connecting rod faces the crankshaft and the narrow sides face each other.**

CAUTION: **Always replace the connecting rod bolts whenever they are loosened or removed.**

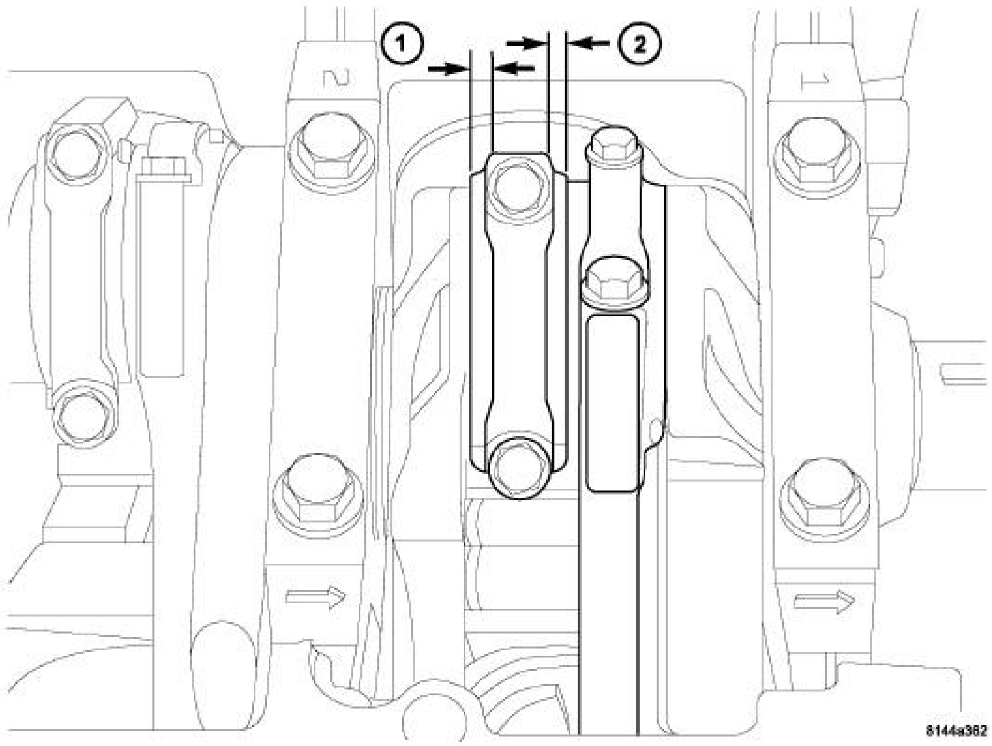

Fig. 149: Identifying Connecting Rod Proper Installation
Courtesy of CHRYSLER GROUP, LLC

12. Verify the connecting rods are properly installed, the wide side (1) of the connecting rod is facing towards the crankshaft and the narrow sides (2) of the connecting rods face each other.
13. Lubricate the new rod cap bolts with clean engine oil, install and tighten to the proper specification. Refer to **TORQUE SPECIFICATIONS**.

CAUTION: **When removing and installing the pistons and connecting rods, do not damage the piston oil cooler jets. If the jets are bent, engine damage may occur.**

14. Position the piston oil cooler jet(s) (1).
15. Install the piston oil cooler jet retaining bolt(s) (2) and tighten to proper specification. Refer to **TORQUE SPECIFICATIONS**.
16. Install the oil pan and oil pump pickup tube and oil pan. Refer to **PAN, OIL, INSTALLATION**.
17. Install the cylinder head(s). Refer to **CYLINDER HEAD, INSTALLATION**.
18. Connect the negative battery cable.
19. Start the engine and check for leaks.

SOLENOID, MULTIPLE DISPLACEMENT

DESCRIPTION

DESCRIPTION

The Multi Displacement System (MDS) selectively deactivates cylinders 1, 4, 6, and 7 to improve fuel economy. It has two modes of operation:

- 8 cylinders for acceleration and heavy loads
- 4 cylinders for cruising and city traffic

The main components of the Multi Displacement System are:

- Unique MDS camshaft
- Deactivating roller lifters
- 4 control valve solenoids
- Control valve solenoid wiring harness
- Oil temperature sensor

OPERATION

OPERATION

Cylinder Deactivation

- Trap an exhaust charge from a normal combustion event
- Normal combustion event
- Deactivate the exhaust valve
- Deactivate the intake valve
- Piston is an air spring
- Cylinders deactivated in firing sequence

Cylinder Reactivation

- Normal combustion event
- Activate the exhaust valve
- Activate the intake valve
- Empty the cylinder
- Cylinders reactivated in firing sequence

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - MDS SOLENOID

The Multi-Displacement System (MDS) has the following detectable issues:

- Solenoid circuit
- Fail to deactivate a cylinder(s)
- Fail to reactivate a cylinder(s)
- Low oil pressure

CONDITION	POSSIBLE CAUSES	CORRECTION
MDS does not activate	1. Low oil pressure	1. Check for proper oil pressure
	2. Bad oil temperature sensor	2. Replace the oil temperature sensor
-	3. Malfunctioning MDS solenoid	3. Replace the MDS solenoid
-	4. Malfunctioning MDS lifter	4. Replace lifter(s)
MDS does not deactivate	1. Low oil pressure	1. Check or proper oil pressure
	2. Bad oil temperature sensor	2. Replace the oil temp sensor

CONDITION	POSSIBLE CAUSES	CORRECTION
-	3. Malfunctioning MDS solenoid	3. Replace the MDS solenoid
-	4. Malfunctioning MDS lifter(s)	4. Replace lifter(s)

LUBRICATION

DESCRIPTION

DESCRIPTION

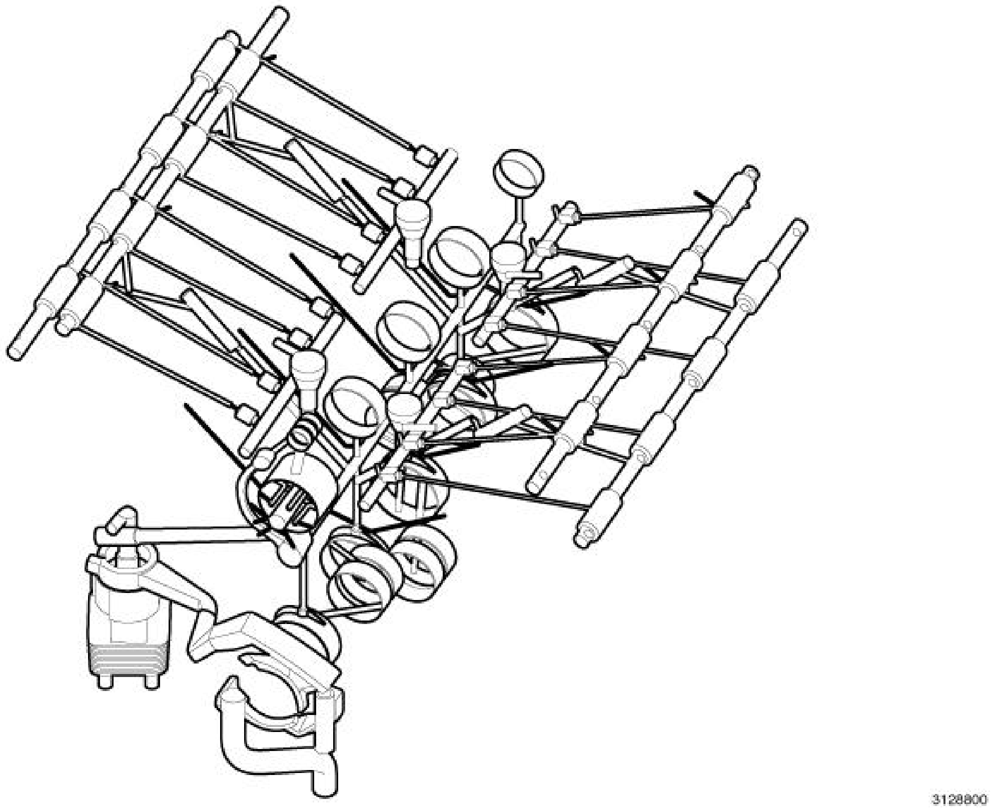

Fig. 182: 6.4L Lubrication System

The lubrication system is a full flow filtration pressure feed type system.

DIAGNOSIS AND TESTING

CHECKING ENGINE OIL PRESSURE

1. Remove oil pressure sending unit and install gauge assembly (special tool #C-3292A, Gauge, Pressure).
2. Run engine until thermostat opens.
3. Check oil pressure gauge:
    - Curb Idle - 25 kPa (4 psi) minimum
    - 3000 RPM - 170 - 758 kPa (25 - 110 psi)
4. If oil pressure is 0 at idle, shut off engine. Check for a clogged oil pick-up screen or a pressure relief valve stuck open.

ENGINE OIL LEAK

Begin with a thorough visual inspection of the engine, particularly at the area of the suspected leak. If an oil leak source is not readily identifiable, the following steps should be followed:

1. Do not clean or degrease the engine at this time because some solvents may cause rubber to swell thus temporarily stopping the leak.
2. Add an oil soluble dye (use as recommended by manufacturer). Start the engine and let idle for approximately 15 minutes. Check the oil dipstick to make sure the dye is thoroughly mixed as indicated with a bright yellow color under a black light.
3. Using a black light, inspect the entire engine for fluorescent dye, particularly at the suspected area of oil leak. If the oil leak is found and identified, repair per service information procedures.
4. If dye is not observed, drive the vehicle at various speeds for approximately 24 km (15 miles), and repeat inspection.

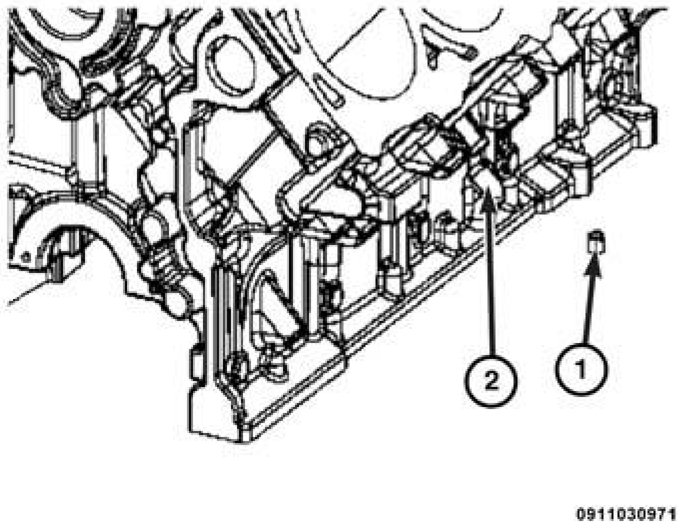

Fig. 183: Engine Oil Pan Plug Component Location
Courtesy of CHRYSLER GROUP, LLC

NOTE: **If the oil indicator tube is located in the engine oil pan. A plug (1) is inserted into the hole on the engine block (2). Validation of the plug is required when the engine block has been replaced.**

AIR LEAK DETECTION TEST METHOD

1. Remove the PCV valve, cap or plug the PCV valve port at the intake manifold.
2. Attach an air hose with a pressure gauge and regulator onto the dipstick tube.

CAUTION: **Do not subject the engine assembly to more than 20.6 kPa (3 PSI) of test pressure.**

3. Gradually apply air pressure from 1 psi to 2.5 psi maximum while applying soapy water at the suspected source. Adjust the regulator to the suitable test pressure that provide the best bubbles which will pinpoint the leak source. If the oil leak is detected and identified, repair per service information procedures.
4. If the leakage occurs at the rear oil seal area, proceed with the **INSPECTION FOR REAR SEAL AREA LEAKS**.
5. If no leaks are detected, turn off the air supply and remove the air hose from the dipstick tube.

6. Remove the PCV port plug or cap at the intake manifold and install the PCV valve.
7. Clean the oil off the suspect oil leak area using a suitable solvent. Drive the vehicle at various speeds approximately 24 km (15 miles). Inspect the engine for signs of an oil leak by using a black light. If the oil leak is found and identified, repair per service information procedures.

INSPECTION FOR REAR SEAL AREA LEAKS

Since it is sometimes difficult to determine the source of an oil leak in the rear seal area of the engine, a more involved inspection is necessary. The following steps should be followed to help pinpoint the source of the leak.

If the leakage occurs at the crankshaft rear oil seal area:

1. Disconnect and isolate the negative battery cable.
2. Raise and support the vehicle.
3. Remove torque converter or clutch housing inspection cover.
4. Using a black light and inspect the rear of the engine block for evidence of oil.

   Circular spray pattern on the rear of the engine block generally indicates:

   - Rear crankshaft oil seal
   - Damaged crankshaft

   Oil running straight down the back of the engine block generally indicates:

   - Porous engine block
   - Camshaft core hole plug
   - Oil gallery pipe plug
   - Oil pan gasket
5. If no leaks are detected, pressurize the crankcase as outlined in the **AIR LEAK DETECTION TEST METHOD**.

   CAUTION: Do not subject the engine assembly to more than 20.6 kPa (3 PSI) of test pressure.

6. If the leak is not detected, very slowly turn the crankshaft and watch for leakage. If a leak is detected between the crankshaft and crankshaft oil seal while slowly turning the crankshaft, it is possible the crankshaft seal surface is damaged. The seal area on the crankshaft could have minor nicks or scratches that can be polished out with emery cloth.

   CAUTION: Use extreme caution when crankshaft polishing is necessary to remove minor nicks and scratches. The crankshaft seal flange is machined specifically to complement the function of the rear oil seal.

7. For bubbles that remain steady with shaft rotation, no further inspection can be done until disassembled.

SOLENOID, VARIABLE VALVE TIMING (VVTS), EXHAUST

DESCRIPTION

DESCRIPTION

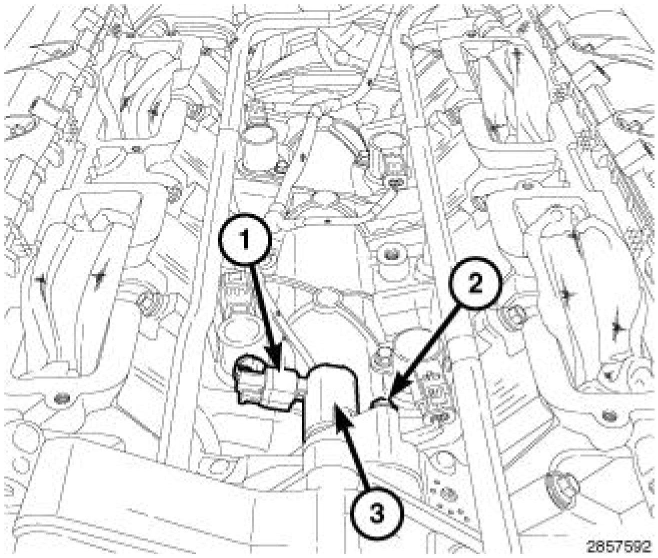

Fig. 184: Oil Control Valve, Electrical Connector & Retaining Bolt
Courtesy of CHRYSLER GROUP, LLC

The 6.4L engine is equipped with Variable Valve Timing (VVT). This system uses a Variable Valve Timing Solenoid (VVTS) to control the oil pressure to direct oil pressure to the camshaft phaser assembly. The camshaft phaser assembly advances and/or retards camshaft timing to improve engine performance, mid-range torque, idle quality, fuel economy and reduce emissions. The VVTS (3) is located under the intake manifold.

OPERATION

OPERATION

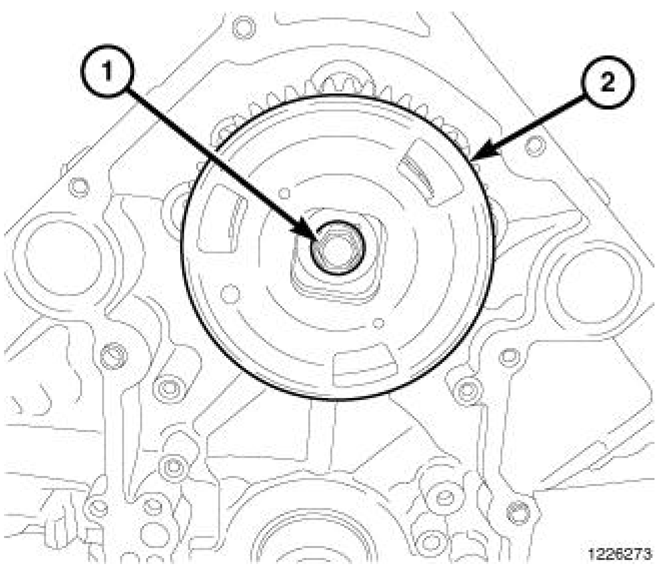

Fig. 185: Camshaft Phaser & Bolt
Courtesy of CHRYSLER GROUP, LLC

The Variable Cam Timing (VCT) assembly is actuated with engine oil pressure. The oil flow to the VCT assembly is controlled by an Variable Valve Timing Solenoid (VVTS). The VVTS consists of a Pulse Width Modulated (PWM) solenoid and a spool valve. The Powertrain Control Module (PCM) actuates the VVTS to

control oil flow through the spool valve into the VCT assembly. The VCT assembly consists of a rotor and a stator/sprocket. The stator/sprocket is connected to the timing chain. The rotor is connected to the camshaft. Oil flow into the VCT assembly rotates the rotor with respect to the stator, thus rotating the camshaft with respect to the stator/sprocket. This will rotate both the intake and exhaust lobes on the camshaft by the same amount. The intake and exhaust lobes can not be individually controlled with this VCT system. An infinitely variable valve timing position can be achieved within the limits of the hardware. The camshaft position sensor monitors the position of the camshaft with respect to the crankshaft and provides feedback to the PCM.

COOLER, OIL

DESCRIPTION

DESCRIPTION

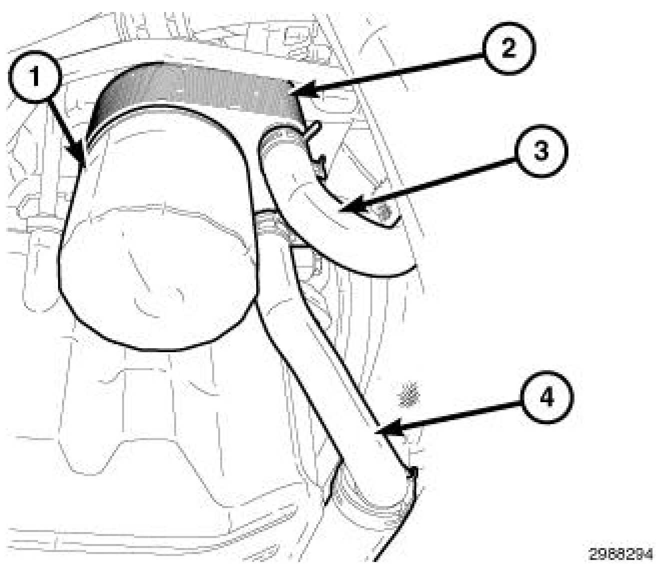

Fig. 190: Oil Filter, Oil Cooler & Hoses

The engine oil cooler (2) is engineered for maximum cooling efficiency with no restriction in oil flow. The oil cooler is a stack plate design coolant-to-oil heat exchanger.

The oil cooler (2) is mounted between the oil filter (1) and the engine block. The oil cooler uses the radiator coolant system; coolant is circulated through two coolant hoses to maintain a consistent engine oil temperature.

REMOVAL

REMOVAL

CAUTION: If the engine encounters a catastrophic failure, the engine oil cooler and lines must be replaced or damage to the new engine and/or components could result.

OIL

STANDARD PROCEDURE

STANDARD PROCEDURE - ENGINE OIL SERVICE

CRANKCASE OIL LEVEL INSPECTION

The oil level indicator is located on the right side of the engine.

CAUTION: Do not overfill crankcase with engine oil, pressure loss or oil foaming can result.

Inspect the engine oil level approximately every 800 kilometers (500 miles). Unless the engine has exhibited loss of oil pressure, run the engine for about ten minutes before checking the oil level. Checking the engine oil level on a cold engine is not accurate.

To ensure proper lubrication of an engine, the engine oil must be maintained at an acceptable level. The acceptable levels are indicated between the ADD and SAFE marks on the engine oil level indicator.

1. Position the vehicle on the level surface.
2. With the engine off, allow approximately five minutes for the oil to settle to the bottom of the crankcase and then remove the engine oil level indicator.
3. Wipe the oil level indicator clean.
4. Install the oil level indicator and verify it is seated in the tube.

5. Remove the oil level indicator, with the handle held above the tip, observe the oil level reading.
6. Add oil only if the level is below the ADD mark on the oil level indicator.

ENGINE OIL CHANGE

Change the engine oil at the mileage and time intervals described in the Maintenance Schedules. Refer to **MAINTENANCE SCHEDULES, DESCRIPTION** .

Run the engine until it reaches normal operating temperature.

1. Remove the oil fill cap.
2. Raise and support the vehicle. Refer to **HOISTING, STANDARD PROCEDURE** .
3. Remove the belly pan. Refer to **BELLY PAN, REMOVAL** or **BELLY PAN, ENGINE, REMOVAL** .
4. Place a suitable drain pan under the oil pan drain.
5. Remove the drain plug from the oil pan and allow the oil to drain.

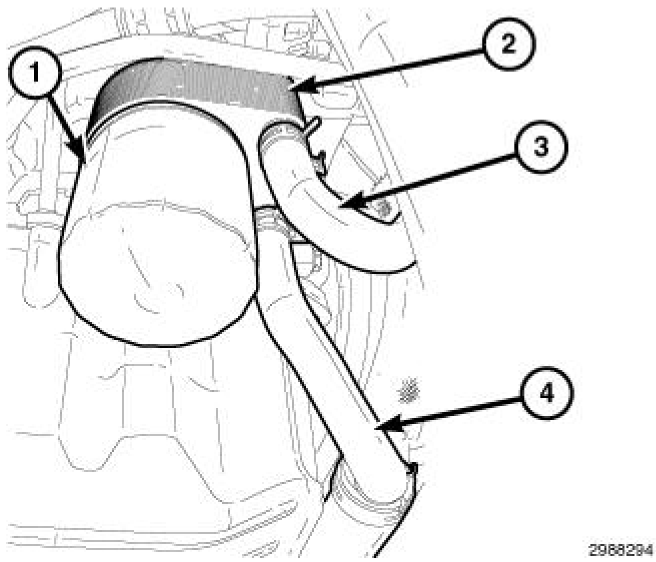

Fig. 206: Oil Filter, Oil Cooler & Hoses
Courtesy of CHRYSLER GROUP, LLC

6. Remove the oil filter (1).
7. Lightly lubricate the NEW oil filter gasket with clean engine oil.

NOTE: Do not over tighten the oil filter.

8. Thread the oil filter onto the oil cooler (2) oil filter boss.
9. When the oil filter gasket makes contact with the oil cooler sealing surface, hand tighten the oil filter one half turn, or 180Â°.
10. Clean any residual oil that may have dripped onto the oil cooler hoses (3, 4)

    .

11. Inspect the drain plug threads for stretching or other damage and replace if necessary.
12. Install the drain plug and tighten to the proper specification. Refer to **TORQUE SPECIFICATIONS**.

13. Install the belly pan. Refer to **BELLY PAN, INSTALLATION** or **BELLY PAN, ENGINE, INSTALLATION** .
14. Lower the vehicle and fill the crankcase with the specified type and amount of engine oil described in **OIL**.
15. Install the oil fill cap.
16. Start the engine and check for leaks.
17. Stop the engine and check the oil level.

NOTE: Care should be exercised when disposing of used engine oil.

PAN, OIL

REMOVAL

REMOVAL

1. Disconnect the negative battery cable.
2. Remove the intake manifold. Refer to **MANIFOLD, INTAKE, REMOVAL**.
3. Remove the engine oil dipstick and tube from the oil pan.

NOTE: **Do not pry on the oil pan or oil pan gasket. The oil pan gasket is integral to the engine windage tray and does not come out with the oil pan.**

NOTE: **The horizontal M10 retaining bolts (11, 12, 15, 18) are 5 mm longer in length then the vertical M10 retaining bolts (20, 21, 22, 23) and must be reinstalled in their original locations.**

13. Raise and support the vehicle. Refer to **HOISTING, STANDARD PROCEDURE** .
14. Remove the M10 retaining bolts (horizontal 11, 12, 15, 18 and vertical 20, 21, 22, 23) from the rear of the oil pan to the transmission.
15. Remove the M6 retaining bolts and remove the oil pan.

CAUTION: Oil pump pressure relief valve and spring should not be removed from the oil pump. If these components are disassembled and or removed from the pump the entire oil pump assembly must be replaced.

1. Remove the pump cover.
2. Clean all parts thoroughly. The mating surface of the oil pump housing should be smooth. If the oil pump cover is scratched or grooved the oil pump assembly should be replaced.
3. Slide the outer rotor into the body of the oil pump. Press the outer rotor to one side of the oil pump body and measure the clearance between the outer rotor (2) and the body. If the measurement is 0.235 mm (0.009 in.) or greater the oil pump assembly must be replaced.

SENSOR, OIL PRESSURE

DESCRIPTION

DESCRIPTION

The oil pressure sensor uses the following three circuits:

- Signal circuit to the PCM
- Sensor ground circuit through the PCM
- 5 volt reference circuit from the PCM

The oil pressure sensor returns a voltage signal back to the PCM with reference to oil pressure. Ground for the sensor is supplied by the PCM.

The oil pressure sensor is located on the right side of the engine block. The sensor screws into the engines main oil gallery.

REMOVAL

REMOVAL

1. Remove the generator. Refer to **GENERATOR, REMOVAL** .
2. Position the generator aside to gain access to the oil pressure sensor.

SENSOR, OIL TEMPERATURE

DESCRIPTION

DESCRIPTION

The oil temperature sensor uses the following two circuits:

- Signal circuit to the PCM
- Ground circuit from the PCM

The oil temperature sensor is a Negative Thermal Coefficient sensor. The resistance of the sensor changes as oil temperature changes. This results in different output voltages back to the PCM.

The oil temperature sensor is located on the right side of the engine block.

REMOVAL

REMOVAL

1. Remove the generator. Refer to **GENERATOR, REMOVAL** .
2. Position the generator aside to gain access to the oil temperature sensor.

MANIFOLDS

MANIFOLD, EXHAUST

DESCRIPTION

DESCRIPTION

The exhaust manifolds are tube in shell air gap design to maximize durability and performance. The exhaust manifolds are made of stainless steel stamped shells and stainless steel tubes with a powdered metal outlet. A layered graphite over perforated steel manifold gasket is used to provide sealing to the cylinder head.

OPERATION

OPERATION

The exhaust manifolds collect the engine exhaust gases exiting the combustion chambers and then channels the exhaust gases to the exhaust pipes/catalytic converters.

REMOVAL

REMOVAL

1. Disconnect and isolate the negative battery cable.

NOTE: The left side shown in illustration. Right side similar.

2. Remove cylinder head. Refer to **CYLINDER HEAD, REMOVAL**.

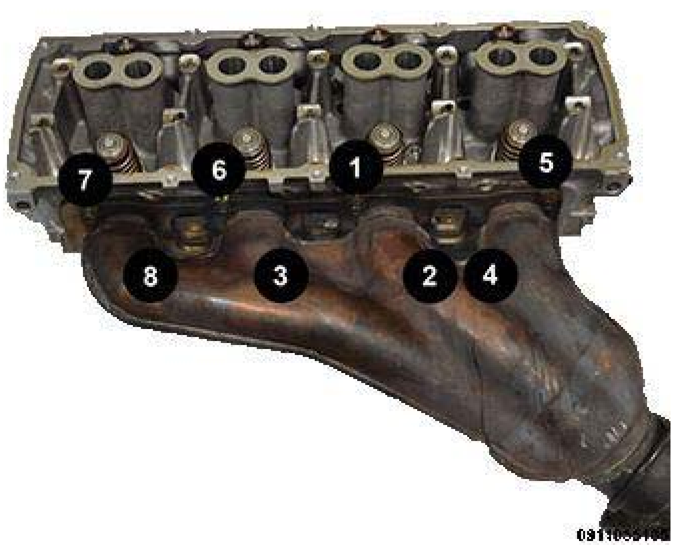

Fig. 235: Exhaust Manifold Removal/Tightening Sequence
Courtesy of CHRYSLER GROUP, LLC

3. Remove the exhaust manifold bolts using the sequence shown in illustration, starting at eight and going backwards.

CLEANING

CLEANING

Clean the mating surfaces on cylinder head and manifold. Wash with solvent and blow dry with compressed air.

INSPECTION

INSPECTION

Inspect the exhaust manifold for cracks.

Inspect the mating surface of the exhaust manifold for flatness with a straight edge. The exhaust manifold gasket surface must be flat and within 0.67 mm (0.0264 in.) overall.

INSTALLATION

INSTALLATION

1. Clean the sealing surfaces of the exhaust manifold and cylinder head.

NOTE: **Left side shown in illustration. Right side similar.**

2. Using a new exhaust manifold gasket, position the exhaust manifold to the cylinder head.

3. First install the **NEW** exhaust manifold retaining bolts finger tight.
4. Using the sequence shown in illustration, tighten the retaining bolts to the proper specification. Refer to **TORQUE SPECIFICATIONS**.
5. Install the cylinder head. Refer to **CYLINDER HEAD, INSTALLATION**.
6. Connect the negative battery cable.
7. Start the engine and check for leaks.

MANIFOLD, INTAKE

DESCRIPTION

DESCRIPTION

CAUTION: If the engine has experienced a catastrophic failure, THE INTAKE MANIFOLD MUST BE REPLACED!

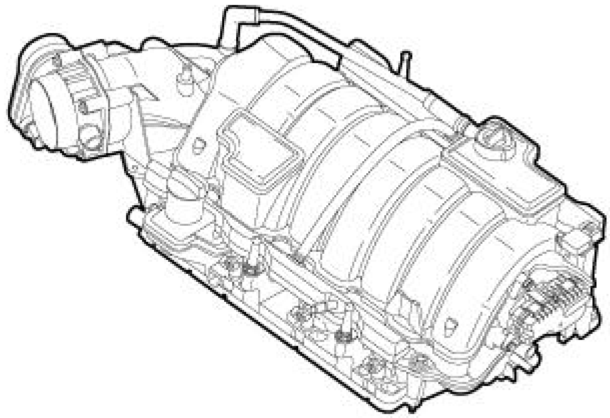

Fig. 237: Intake Manifold
Courtesy of CHRYSLER GROUP, LLC

The intake manifold is made of a composite material and features a dual shaft Short Runner Valve (SRV) system to maximize both low end torque and peak power. The SRV is bolted to the rear of the intake manifold and can be service separately from the manifold. The manifold uses a single plane sealing system with individual port seals and a separate PCV port seal to prevent leaks.

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - INTAKE MANIFOLD LEAKAGE

An intake manifold air leak is characterized by lower than normal manifold vacuum. Also, one or more cylinders may not be functioning.

WARNING: Use extreme caution when the engine is operating. Do not stand in a direct line with the fan. Do not put your hands near the pulleys, belts or the fan. Do not wear loose clothing. Failure to follow this warning may result in serious or fatal injury.

1. Start the engine.
2. Spray a small stream of water at the suspected leak area.
3. If a change in RPM is observed the area of the suspected leak has been found.
4. Repair as required.

REMOVAL

REMOVAL

1. Perform the fuel system pressure release procedure. Refer to **FUEL DELIVERY, GAS, STANDARD PROCEDURE** .
2. Disconnect and isolate the negative battery cable.

3. Remove the engine covers (1).
4. Disconnect the fuel supply line. Refer to **FITTING, QUICK CONNECT, STANDARD PROCEDURE**
.
5. Remove the air cleaner body. Refer to **BODY, AIR CLEANER, REMOVAL**.
6. Disconnect the brake booster hose and the vapor purge hose.

7. Disconnect the wire harness connectors from the following components:
   - Manifold Absolute Pressure (MAP) Sensor
   - Short Runner Valve (SRV)
   - Fuel Injectors
   - Electronic Throttle Control (ETC)

8. Using the sequence shown in illustration, remove the intake manifold retaining bolts.
9. Remove the intake manifold and throttle body as an assembly from the vehicle.

CLEANING

CLEANING

NOTE: **There is NO approved repair procedure for the intake manifold. If severe damage is found during inspection, the intake manifold must be replaced.**

Before installing the intake manifold thoroughly clean the mating surfaces. Use a suitable cleaning solvent, then air dry.

INSPECTION

INSPECTION

1. Inspect the intake manifold sealing surface for cracks, nicks and distortion.
2. Inspect the intake manifold vacuum hose fittings for looseness or blockage.

INSTALLATION

INSTALLATION

NOTE: **The intake manifold seals (1, 3) may be used again, provided no cuts, tears, or deformation have occurred.**

1. Inspect the intake manifold seals and replace if necessary.

   NOTE: **If reinstalling the original manifold, apply MoparÃ® Lock & Seal Adhesive to the intake manifold bolts. Not required when installing a new manifold.**

2. If required, apply MoparÃ® Lock & Seal Adhesive to the intake manifold bolts.

3. Position the intake manifold (2).

4. Using the sequence shown in illustration, install the intake manifold retaining bolts and tighten to 12 N.m (9 ft. lbs.).
5. Connect the fuel supply line. Refer to **FITTING, QUICK CONNECT, STANDARD PROCEDURE** .
6. Connect the brake booster hose and the EVAP purge hose.
7. Connect the electrical connectors to the following components:
   - Manifold Absolute Pressure (MAP) Sensor
   - Short Runner Valve (SRV)
   - Fuel Injectors
   - Electronic Throttle Control (ETC)
8. Install the air cleaner body. Refer to **BODY, AIR CLEANER, INSTALLATION**.

TENSIONER, ENGINE TIMING

DESCRIPTION

DESCRIPTION

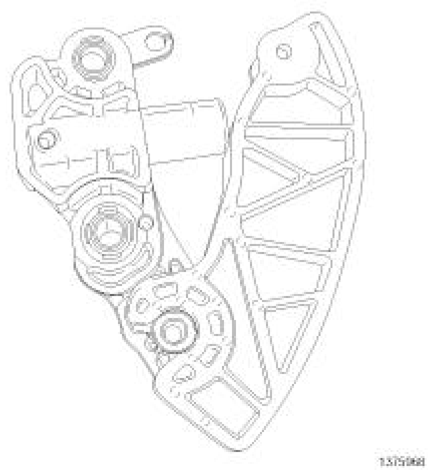

Fig. 269: Timing Chain Tensioner Arm
Courtesy of CHRYSLER GROUP, LLC

The timing chain tensioner is a spring loaded design. It consists of two chain guide shoes. One shoe is fixed in place and the other is spring loaded to keep tension on the chain.

OPERATION

OPERATION

The timing chain tension is maintained by routing the timing chain through the tensioner assembly. The tensioner assembly consists of two chain guide shoes. One shoe is fixed in place and the other is spring loaded to maintain the correct timing chain tension.

REMOVAL

For the removal procedure, refer to **CHAIN AND SPROCKETS, TIMING, REMOVAL**.

INSTALLATION

Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of cleaning, inspection, and assembly processes are included.

ENGINE IDENTIFICATION

Engine may be identified from Vehicle Identification Number (VIN) stamped on a metal tab. Metal tab may be located in different locations depending on manufacturer. Engine identification number or serial number is located on cylinder block. Location varies with each manufacturer.

INSPECTION PROCEDURES

section for complete overhaul procedures and specifications for the vehicle being repaired.

Engine components must be inspected to meet manufacturer's specifications and tolerances during overhaul. Proper dimensions and tolerances must be met to obtain proper performance and maximum engine life.

Micrometers, depth gauges and dial indicator are used for checking tolerances during engine overhaul. Magnaflux, Magnaglo, dye-check, ultrasonic and x-ray inspection procedures are used for parts inspection.

MAGNETIC PARTICLE INSPECTION

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Magnaflux & Magnaglo

Magnaflux is an inspection technique used to locate material flaws and stress cracks. Component is subjected to a strong magnetic field. Entire component or a localized area can be magnetized. Component is coated with either a wet or dry material that contains fine magnetic particles.

Cracks which are outlined by the particles cause an interruption of magnetic field. Dry powder method of Magnaflux can be used in normal lighting and crack appears as a bright line.

Fluorescent liquid is used along with a Black light in the Magnaglo Magnaflux system. Darkened room is required for this procedure. The crack will appear as a glowing line. Complete demagnetizing of component upon completion is required on both procedures. Magnetic particle inspection applies to ferrous materials only.

PENETRANT INSPECTION

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Zyglo

The Zyglo process coats material with a fluorescent dye penetrant. Component is often warmed to expand cracks that will be penetrated by the dye. Using darkened room and Black light, component is inspected for cracks. Crack will glow brightly.

Developing solution is often used to enhance results. Parts made of any material, such as aluminum cylinder heads or plastics, may be tested using this process.

Dye Check

Penetrating dye is sprayed on the previously cleaned component. Dye is left on component for 5-45 minutes, depending upon material density. Component is then wiped clean and sprayed with a developing solution. Surface cracks will show up as a bright line.

ULTRASONIC INSPECTION

Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

If an expensive part is suspected of internal cracking, ultrasonic testing is used. Sound waves are used for component inspection.

X-RAY INSPECTION

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

This form of inspection is used on highly stressed components. X-ray inspection may be used to detect internal and external flaws in any material.

PRESSURE TESTING

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Cylinder heads can be tested for cracks using a pressure tester. Pressure testing is performed by plugging all but one of the holes of cylinder head and injecting air or water into the open passage.

Leaks are indicated by the appearance of wet or damp areas when using water. When air is used, it is necessary to spray the head surface with a soap solution. Bubbles will indicate a leak. Cylinder head may also be submerged in water heated to specified temperature to check for cracks created during heat expansion.

All components of an engine do not have the same cleaning requirements. Physical methods include bead blasting and manual removal. Chemical methods include solvent blast, solvent tank, hot tank, cold tank and steam cleaning of components.

BEAD BLASTING

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Manual removal of deposits may be required prior to bead blasting, followed by some other cleaning method. Carbon, paint and rust may be removed using bead blasting method. Components must be free of oil and grease prior to bead blasting. Beads will stick to grease or oil soaked areas causing area not to be cleaned.

Use air pressure to remove all trapped residual beads from component after cleaning. After cleaning internal engine parts made of aluminum, wash thoroughly with hot soapy water. Component must be thoroughly cleaned as glass beads will enter engine oil resulting in bearing damage.

CHEMICAL CLEANING

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Solvent tank is used for cleaning oily residue from components. Solvent blasting sprays solvent through a siphon gun using compressed air.

The hot tank, using heated caustic solvents, is used for cleaning ferrous materials only. DO NOT clean aluminum parts such as cylinder heads, bearings or other soft metals using the hot tank. After cleaning, flush parts with hot water.

A non-ferrous part will be ruined and caustic solution will be diluted if placed in the hot tank. Always use eye protection and gloves when using the hot tank.

Use of a cold tank is for cleaning aluminum cylinder heads, carburetors and other soft metals. A less caustic and unheated solution is used. Parts may be left in the tank for several hours without damage. After cleaning, flush parts with hot water.

Steam cleaning, with boiling hot water sprayed at high pressure, is recommended as the final cleaning process when using either hot or cold tank cleaning.

Examples of sheet metal parts are rocker covers, front and side covers, oil pan and bellhousing dust cover. Glass bead blasting or hot tank may be used for cleaning.

Ensure all mating surfaces are flat. Deformed surfaces should be straightened. Check all sheet metal parts for cracks and dents.

Using solvent cleaning or bead blasting, clean manifolds for inspection. If intake manifold has an exhaust crossover, all carbon deposits must be removed. Inspect manifolds for cracks, burned or eroded areas, corrosion and damage to fasteners.

Exhaust heat and products of combustion cause threads of fasteners to corrode. Replace studs and bolts as necessary. On "V" type intake manifolds, sheet metal oil shield must be removed for proper cleaning and inspection. Ensure all manifold parting surfaces are flat and free of burrs.

CYLINDER HEAD REPLACEMENT

REMOVAL

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Remove intake and exhaust manifolds and valve cover. Cylinder head and camshaft carrier bolts (if equipped) should be removed only when engine is cold. On many aluminum cylinder heads, removal while hot will cause cylinder head warpage. Mark rocker arm or overhead cam components for location.

Remove rocker arm components or overhead cam components. Components must be installed in original location. Individual design rocker arms may utilize shafts, ball-type pedestal mounts or no rocker arms. For all design types, wire components together and identify according to corresponding valve. Remove cylinder head bolts. Note length and location. Some applications require cylinder head bolts be removed in proper sequence to prevent cylinder head damage. See **Fig. 1**. Remove cylinder head.

INSTALLATION

NOTE:	**Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.** **Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.**

Ensure all surfaces and head bolts are clean. Check that head bolt holes of cylinder block are clean and dry to prevent block damage when bolts are tightened. Clean threads with tap to ensure accurate bolt torque.

Install head gasket on cylinder block. Some manufacturers may recommend sealant be applied to head gasket prior to installation. Note that all holes are aligned. Some gasket applications may be marked so that certain area faces upward. Install cylinder head using care not to damage head gasket. Ensure cylinder head is fully seated on cylinder block.

Some applications require head bolts be coated with sealant prior to installation. This is done if head bolts are exposed to coolant passages. Some applications require head bolts be coated with light coat of engine oil.

Install head bolts. Head bolts should be tightened in proper steps and sequence to specification. See **Fig. 1**. Install remaining components. Tighten all bolts to specification. Adjust valves if required. See VALVE ADJUSTMENT.

NOTE:	**Some manufacturers require that head bolts be retightened after specified amount of operation. This must be done to prevent head gasket failure.**

VALVE ADJUSTMENT

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Engine specifications will indicate valve train clearance and temperature at which adjustment is to be made on most models. In most cases, adjustment will be made with a cold engine. In some cases, both a cold and a hot clearance will be given for maintenance convenience.

On some models, adjustment is not required. Rocker arms are tightened to specification and valve lash is automatically set. On some models with push rod actuated valve train, adjustment is made at push rod end of rocker arm while other models do not require adjustment.

Clearance will be checked between tip of rocker arm and tip of valve stem in proper sequence using a feeler gauge. Adjustment is made by rotating adjusting screw until proper clearance is obtained. Lock nut is then tightened. Engine will be rotated to obtain all valve adjustments to manufacturer's specifications.

Some models require hydraulic lifter to be bled down and clearance measured. Push rods of different length can be used to obtain proper clearance. Clearance will be checked between tip of rocker arm and tip of valve stem in proper sequence using a feeler gauge.

Overhead cam engines designed without rocker arms actuate valves directly on a cam follower. A hardened, removable disc is installed between the cam lobe and lifter. Clearance will be checked between cam heel and

adjusting disc in proper sequence using a feeler gauge. Engine will be rotated to obtain all valve adjustments.

On overhead cam engines designed with rocker arms, adjustment is made at valve end of rocker arm. Ensure valve to be adjusted is riding on heel of cam on all engines. Clearance will be checked between tip of rocker arm and tip of valve stem in proper sequence using a feeler gauge. Adjustment is made by rotating adjusting screw until proper clearance is obtained. Lock nut is then tightened. Engine will be rotated to obtain all valve adjustments to manufacturer's specifications.

CYLINDER HEAD CLEANING & INSPECTION

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Clean cylinder head and valve components using approved cleaning methods. Inspect cylinder head for cracks, damage or warped gasket surface. Place straightedge across gasket surface. Determine clearance at center of straightedge. Measure across both diagonals, longitudinal center line and across cylinder head at several points. See **Fig. 3**.

On cast iron cylinder heads, if warpage exceeds .003" (.08 mm) in a 6" span, or .006" (.15 mm) over total length, cylinder head must be resurfaced. On most aluminum cylinder heads, if warpage exceeds .002" (.05 mm) in any area, cylinder head must be resurfaced. Warpage specification may vary by manufacturer. If warpage exceeds specification on some cylinder heads, cylinder head must be replaced.

Cylinder head thickness should be measured to determine amount of material which can be removed before replacement is required. Cylinder head thickness must not be less than the manufacturer's specification.

If cylinder head required resurfacing, it may not align properly with intake manifold. On "V" type engines, misalignment is corrected by machining intake manifold surface that contacts cylinder head. Cylinder head may be machined on surface that contacts intake manifold. Using oil stone, remove burrs or scratches from all sealing surfaces.

VALVE SPRINGS

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Inspect valve springs for corroded or pitted valve spring surfaces which may lead to breakage. Polished spring ends caused by a rotating spring indicate that spring surge has occurred. Replace springs showing evidence of these conditions.

Inspect valve springs for squareness using a 90-degree straightedge. See **Fig. 4**. Replace valve spring if out-of-square exceeds manufacturer's specification.

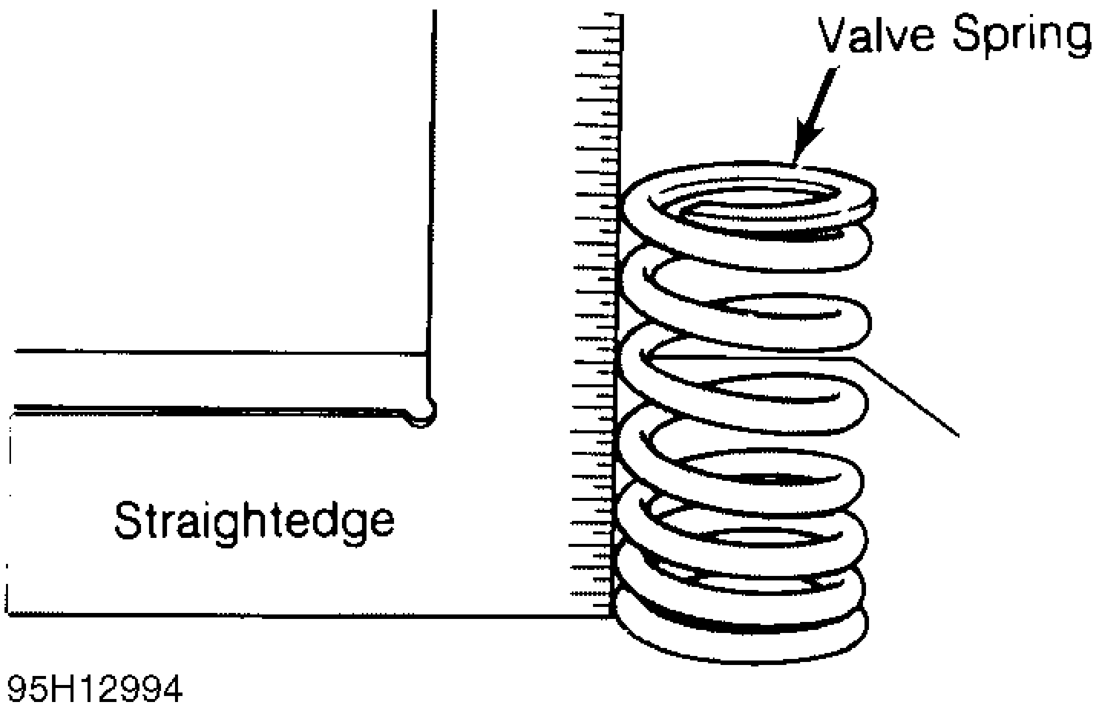

Fig. 4: Checking Valve Spring Squareness

Using vernier caliper, measure free length of all valve springs. Replace springs if not within specification. Using valve spring tester, test valve spring pressure at installed and compressed heights. See **Fig. 5**.

Usually compressed height is installed height minus valve lift. Replace valve spring if not within specification. It is recommended to replace all valve springs when overhauling cylinder head. Valve springs may need to be installed with color coded end or small coils at specified area according to manufacturer.

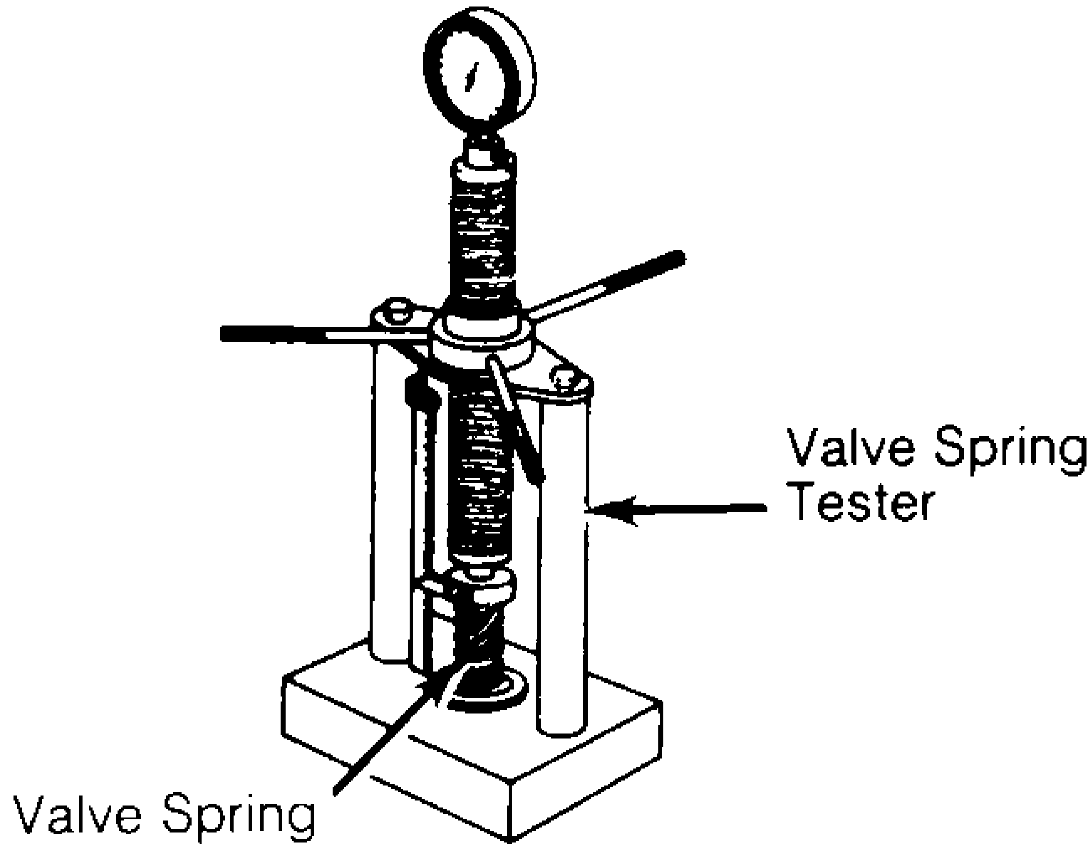

Fig. 5: Checking Valve Spring Pressure

VALVE GUIDE

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Measuring Valve Guide Clearance

Check valve stem-to-guide clearance. Ensure valve stem diameter is within specification. Install valve in valve guide. Install dial indicator assembly on cylinder head with tip resting against valve stem just above valve guide. See **Fig. 6**.

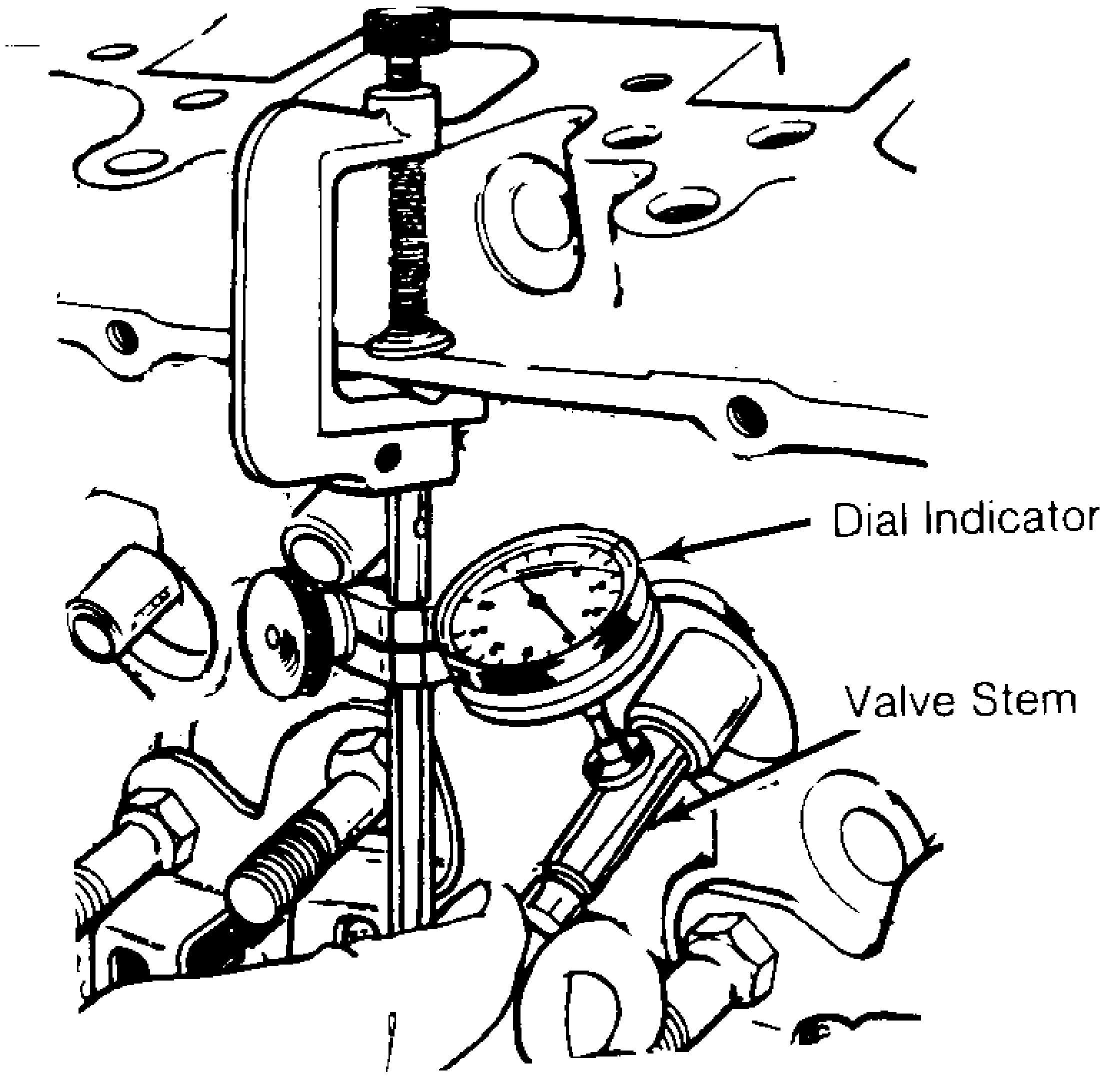

Fig. 6: Measuring Valve Stem-to-Guide Clearance

Lower valve approximately 1/16" below valve seat. Push valve stem against valve guide as far as possible. Adjust dial indicator to zero. Push valve stem in opposite direction and note reading. Clearance must be within specification.

If valve guide clearance exceeds specification, valves with oversize stems may be used and valve guides are reamed to larger size or valve guide must be replaced. On some applications, a false guide is installed, then reamed to proper specification. Valve guide reamer set is used to ream valve guide to obtain proper clearance for new valve.

Reaming Valve Guide

Select proper reamer for size of valve stem. Reamer must be of proper length to provide clean cut through entire

length of valve guide. Install reamer in valve guide and rotate to cut valve guide. See **Fig. 7**.

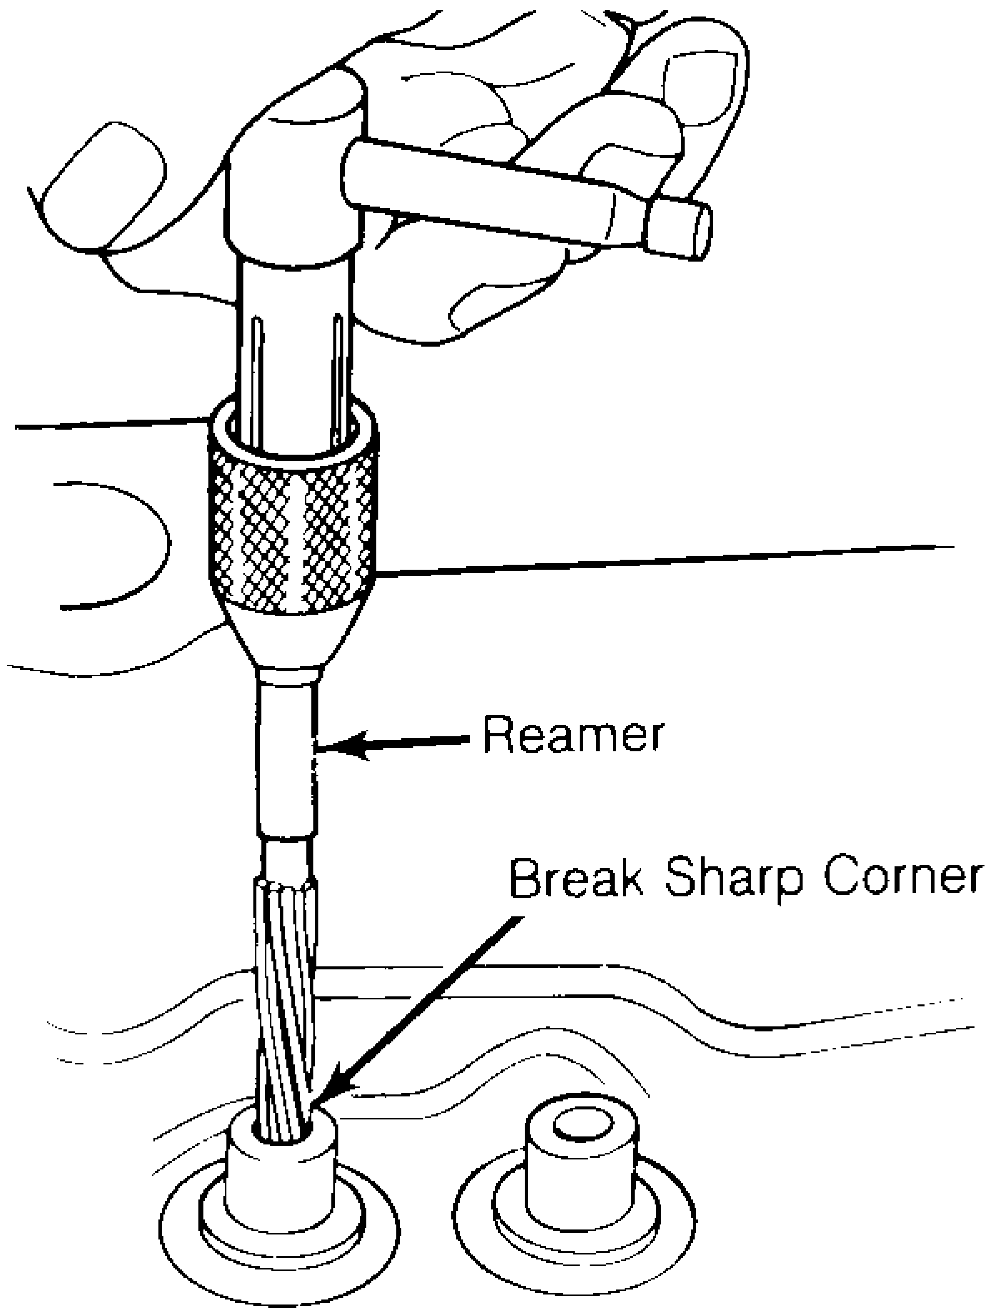

Fig. 7: Reaming Valve Guides

Replacing Valve Guide

Replace valve guide if clearance exceeds specification. Valve guides are either pressed, hammered or shrunk in

place, depending upon cylinder head design and type of metal used.

Remove valve guide from cylinder head by pressing or tapping on a stepped drift. See **Fig. 8**. Once valve guide is installed, distance from cylinder head to top of valve guide must be checked. This distance must be within specification.

Aluminum heads are often heated before installing valve guide. Valve guide is sometimes cooled in dry ice prior to installation. Combination of a heated cylinder head and cooled valve guide ensures a tight guide fit upon assembly. The new guide must be reamed to specification.

VALVES & VALVE SEATS

NOTE:	**Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.** **Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.**

Valve Grinding

Valve stem O.D. should be measured in several areas to indicate amount of wear. Replace valve if not within specification. Valve margin area should be measured to ensure that valve can be ground. See **Fig. 9**.

If valve margin is less than specification, the valves will be burned. Valve must be replaced. Due to minimum margin dimensions during manufacture, some new type valves cannot be reground. Some manufacturers use stellite coated valves that must NOT be machined. Valves can only be lapped into valve seat.

CAUTION:	**Some valves are sodium filled. Extreme care must be used when disposing of damaged or worn sodium-filled valves.**

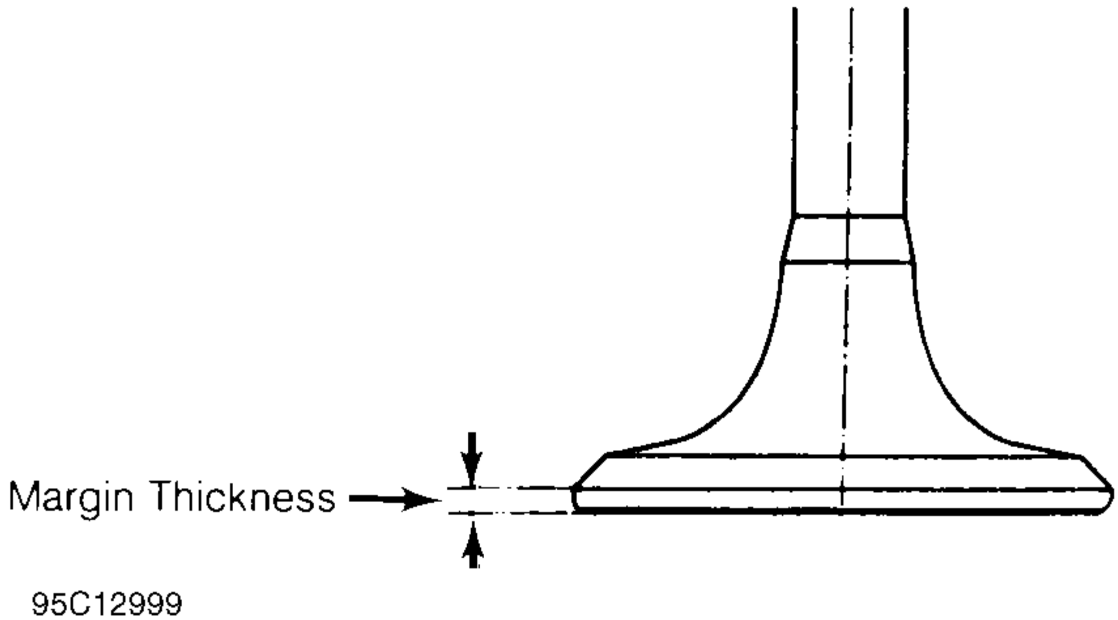

Fig. 9: Measuring Valve Head Margin

Resurface valve to proper angle specification using valve grinding machine. Follow manufacturer's instructions for valve grinding machine. Specifications may indicate a different valve face angle than seat angle. Measure valve margin after grinding. Replace valve if not within specification. Valve stem tip can be refinished using valve grinding machine.

Valve Lapping

During valve lapping of recently designed valves, be sure to follow manufacturer's recommendations. Surface hardening and materials used with some valves do not permit lapping. Lapping process will remove excessive amounts of the hardened surface.

Valve lapping is done to ensure adequate sealing between valve face and seat. Use either a hand drill or lapping stick with suction cup attached.

Moisten and attach suction cup to valve. Lubricate valve stem and guide. Apply a thin coat of fine valve grinding compound between valve and seat. Rotate lapping tool between the palms or with hand drill.

Lift valve upward off the seat and change position often. This is done to prevent grooving of valve seat. Lap valve until a smooth polished seat is obtained. Thoroughly clean grinding compound from components. Valve-to-valve seat concentricity should be checked. See **VALVE SEAT CONCENTRICITY**.

CAUTION: Valve guides must be in good condition and free of carbon deposits prior to valve seat grinding. Some engines contain an induction hardened valve seat. Excessive material removal will damage valve seats.

Valve Seat Grinding

Select coarse stone of correct size and angle for seat to be ground. Ensure stone is true and has a smooth surface. Select correct size pilot for valve guide dimension. Install pilot in valve guide. Lightly lubricate pilot shaft. Install stone on pilot. Move stone off and on the seat approximately 2 times per second during grinding operation.

Select a fine stone to finish grinding operation. Various angle grinding stones are used to center and narrow the valve seat as required. See **Fig. 10**.

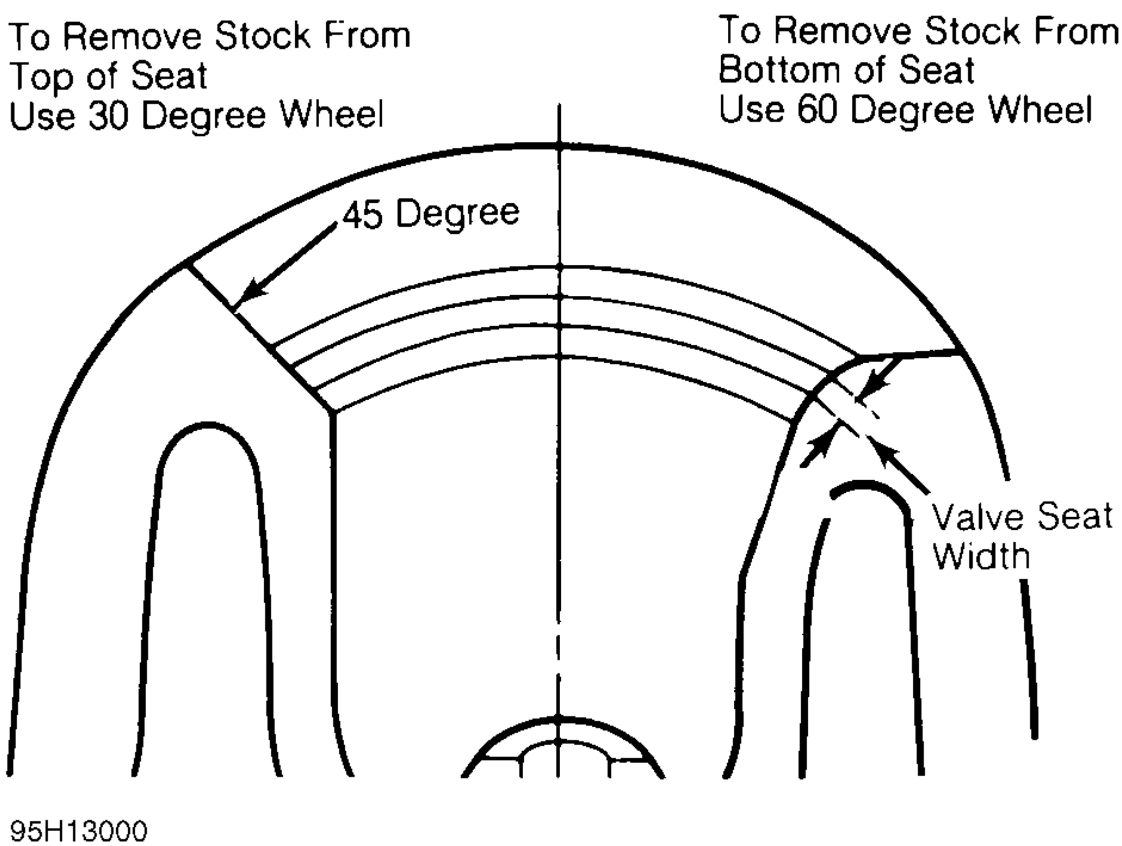

Fig. 10: Adjusting Valve Seat Width

Valve Seat Replacement

Replacement of valve seat inserts is done by cutting out the old insert and machining an oversize insert bore. Replacement oversize insert is usually cooled and the cylinder head is sometimes warmed. Valve seat is pressed into the head. This operation requires specialized machine shop equipment.

Valve Seat Concentricity

Using dial gauge, install gauge pilot in valve guide. Position gauge arm on the valve seat. Adjust dial indicator to zero. Rotate arm 360 degrees and note reading. Runout should not exceed specification.

To check valve-to-valve seat concentricity, coat valve face lightly with Prussian Blue dye. Install valve and rotate it on valve seat. If pattern is even and entire seat is coated at valve contact point, valve is concentric with

the valve seat.

CYLINDER HEAD REASSEMBLY

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Valve Stem Installed Height

Valve stem installed height must be checked when new valves are installed or when valves or valve seats have been ground. Install valve in valve guide. Measure distance from tip of valve stem to spring seat. See **Fig. 11**. Distance must be within specification to allow sufficient clearance for valve operation.

Remove valve and grind valve stem tip if height exceeds specification. Valve tips are surface hardened. DO NOT remove more than .010" (.25 mm) from tip. Chamfer sharp edge of reground valve tip. Recheck valve stem installed height.

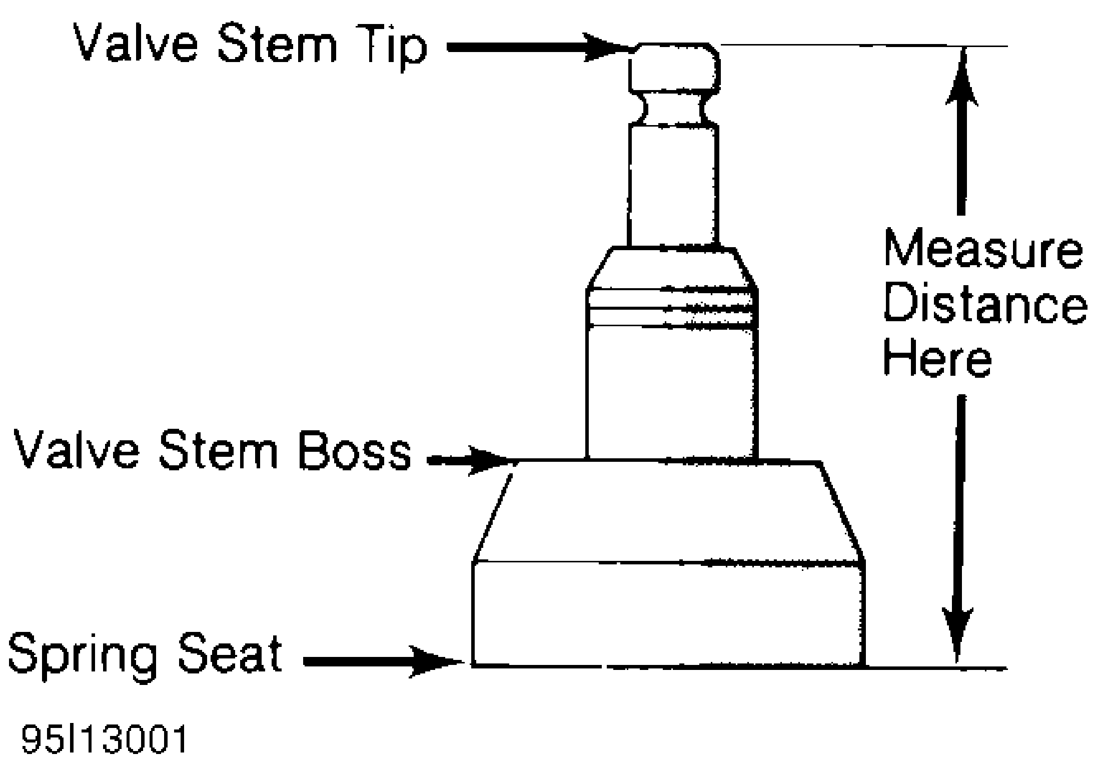

Fig. 11: Measuring Valve Stem Installed Height

VALVE STEM OIL SEALS

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Valve stem oil seals must be installed on valve stem. See **Fig. 2**. Seals are needed due to pressure differential at the ends of valve guides. Atmospheric pressure above intake guide, combined with manifold vacuum below guide, causes oil to be drawn into the cylinder.

Exhaust guides also have pressure differential created by exhaust gas flowing past the guide, creating a low pressure area. This low pressure area draws oil into the exhaust system.

Some manufacturers require that special color code or specified height valve stem oil seal be installed in designated area.

Replacement (On-Vehicle)

Mark rocker arm or overhead cam components for location. Remove rocker arm components or overhead cam components. Components must be installed in original location. Remove spark plugs. Valve stem oil seals may be replaced by holding valves against seats using air pressure.

Air pressure must be installed in cylinder using an adapter for spark plug hole. An adapter can be constructed by welding air hose connection to spark plug body with porcelain removed.

Rotate engine until piston is at top of stroke. Install adapter in spark plug hole. Apply a minimum of 140 psi (9.8 kg/cm^2) line pressure to adapter. Air pressure should hold valve closed. If air pressure does not hold valve closed, check for damaged or bent valve. Cylinder head must be removed for service.

Using valve spring compressor, compress valve springs. Remove valve locks. Carefully release spring compressor. Remove retainer or rotator and valve spring. Remove valve stem oil seal.

If oversize valves have been installed, oversize oil seals must be used. Coat valve stem with engine oil. Install protective sleeve over end of valve stem. Install new oil seal over valve stem and seat on valve guide. Remove protective sleeve. Install spring seat, valve spring and retainer or rotator. Compress spring and install valve locks. Remove spring compressor. Ensure valve locks are fully seated.

Install rocker arms or overhead cam components. Tighten all bolts to specification. Adjust valves if required. Remove adapter. Install spark plugs, valve cover and gasket.

VALVE SPRING INSTALLED HEIGHT

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes**

of cleaning, inspection, assembly and machine shop practice are included.

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Valve spring installed height should be checked during reassembly. Measure height from lower edge of valve spring to the upper edge. DO NOT include valve spring seat or retainer. Distance must be within specification. If valves and/or seats have been ground, a valve spring shim may be required to correct spring height. See **Fig. 12**.

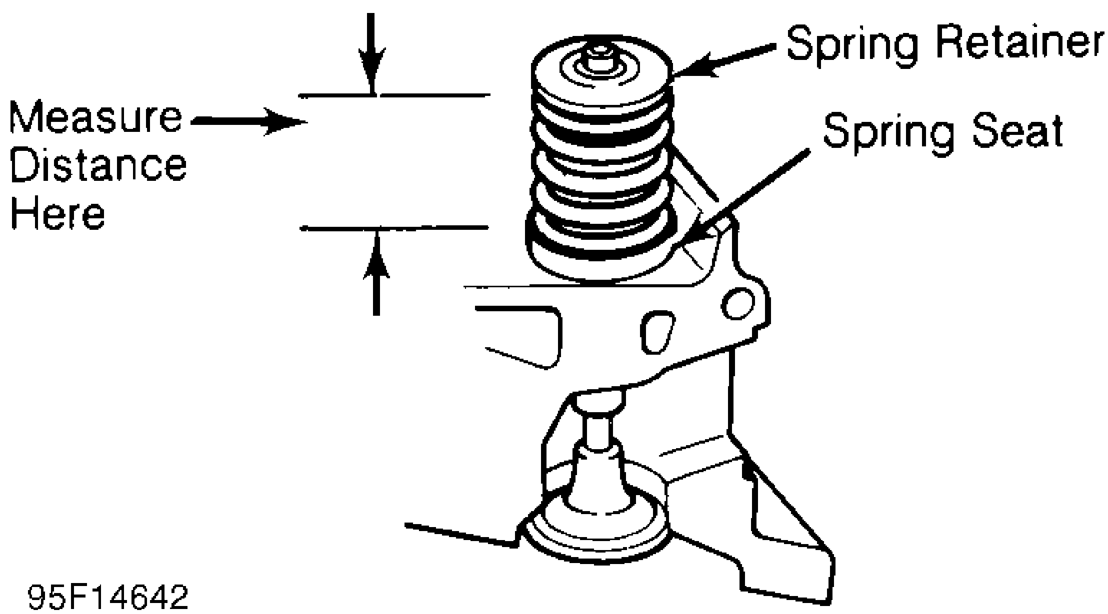

Fig. 12: Measuring Valve Spring Installed Height

ROCKER ARMS & ASSEMBLIES

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Rocker Studs

Rocker studs are either threaded or pressed in place. Threaded studs are removed by locking 2 nuts on the stud. Unscrew the stud by turning the jam nut. Coat new stud threads with Loctite and install. Tighten to

specification.

Pressed-in stud can be removed using a stud puller. Ream stud bore to proper specification and press in a new oversize stud. Pressed-in studs are often replaced by cutting threads in the stud bore to accept a threaded stud.

Rocker Arms & Shafts

Mark rocker arms for location. Remove rocker arm retaining bolts. Remove rocker arms. Inspect rocker arms, shafts, bushings and pivot balls (if equipped) for excessive wear. Inspect rocker arms for wear in valve stem contact area. Measure rocker arm bushing I.D. Replace bushings if excessively worn.

The rocker arm valve stem contact point may be reground, using special fixture for valve grinding machine. Remove minimum amount of material as possible. Ensure all oil passages are clear. Install rocker arm components in original location. Ensure rocker arm is properly seated in push rod. Tighten bolts to specification. Adjust valves if required. See **VALVE ADJUSTMENT**.

PUSH RODS

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Remove rocker arms. Mark push rods for location. Remove push rods. Push rods can be steel or aluminum, solid or hollow. Hollow push rods must be internally cleaned to ensure oil passage to rocker arms is cleaned. Check push rods for damage, such as loose ends on steel tipped aluminum types.

Check push rod for straightness. Roll push rod on a flat surface. Using feeler gauge, check clearance at center. Replace push rod if bent. The push rod can also be supported at each end and rotated. A dial indicator is used to detect a bent area in the push rod.

Lubricate ends of push rod and install push rod in original location. Ensure push rod is properly seated in lifter. Install rocker arm. Tighten bolts to specification. Adjust valves if required. See **VALVE ADJUSTMENT**.

LIFTERS

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Hydraulic Lifters

Before replacing a hydraulic lifter for noisy operation, ensure noise is not caused by worn rocker arms or valve tips. Also ensure sufficient oil pressure exists. Hydraulic lifters must be installed in original location. Remove rocker arm assembly and push rod. Mark components for location. Some applications require intake manifold, cylinder head or lifter cover removal. Remove lifter retainer plate (if used). To remove lifters, use a hydraulic lifter remover or magnet. Different type lifters are used. See **Fig. 13**.

On sticking lifters, disassemble and clean lifter. DO NOT mix lifter components or positions. Parts are select-fitted and are not interchangeable. Inspect all components for wear. Note amount of wear in lifter body-to-camshaft contact area. Surface must have smooth and convex contact face. If wear is apparent, carefully inspect cam lobe.

Inspect push rod contact area and lifter body for scoring or signs of wear. If body is scored, inspect lifter bore for damage and lack of lubrication. On roller type lifters, inspect roller for flaking, pitting, loss of needle bearings and roughness during rotation.

Measure lifter body O.D. in several areas. Measure lifter bore I.D. Ensure components or oil clearance is within specification. Some models offer oversize lifters. Replace lifter if damaged.

If lifter check valve is not operating, obstructions may be preventing it from closing or valve spring may be broken. Clean or replace components as necessary.

Check plunger operation. Plunger should drop to bottom of the body by its own weight when assembled dry. If plunger is not free, soak lifter in solvent to dissolve deposits.

Lifter leak-down test can be performed on lifter. Lifter must be filled with special test oil. New lifters contain special test oil. Using lifter leak-down tester, perform leak-down test following manufacturer's instructions. If leak-down time is not within specifications, replace lifter assembly.

Lifters should be soaked in clean engine oil several hours prior to installation. Coat lifter base, roller (if equipped) and lifter body with ample amount of Molykote or camshaft lubricant. See **Fig. 13**. Install lifter in original location. Install remaining components. Valve lash adjustment is not required on most hydraulic lifters. Preload of hydraulic lifter is automatic. Some models may require adjustment.

NOTE: **Some manufacturers require that a crankcase conditioner be added to engine oil and engine operated for specified amount of time to aid in lifter break-in procedure if new lifters or camshaft are installed.**

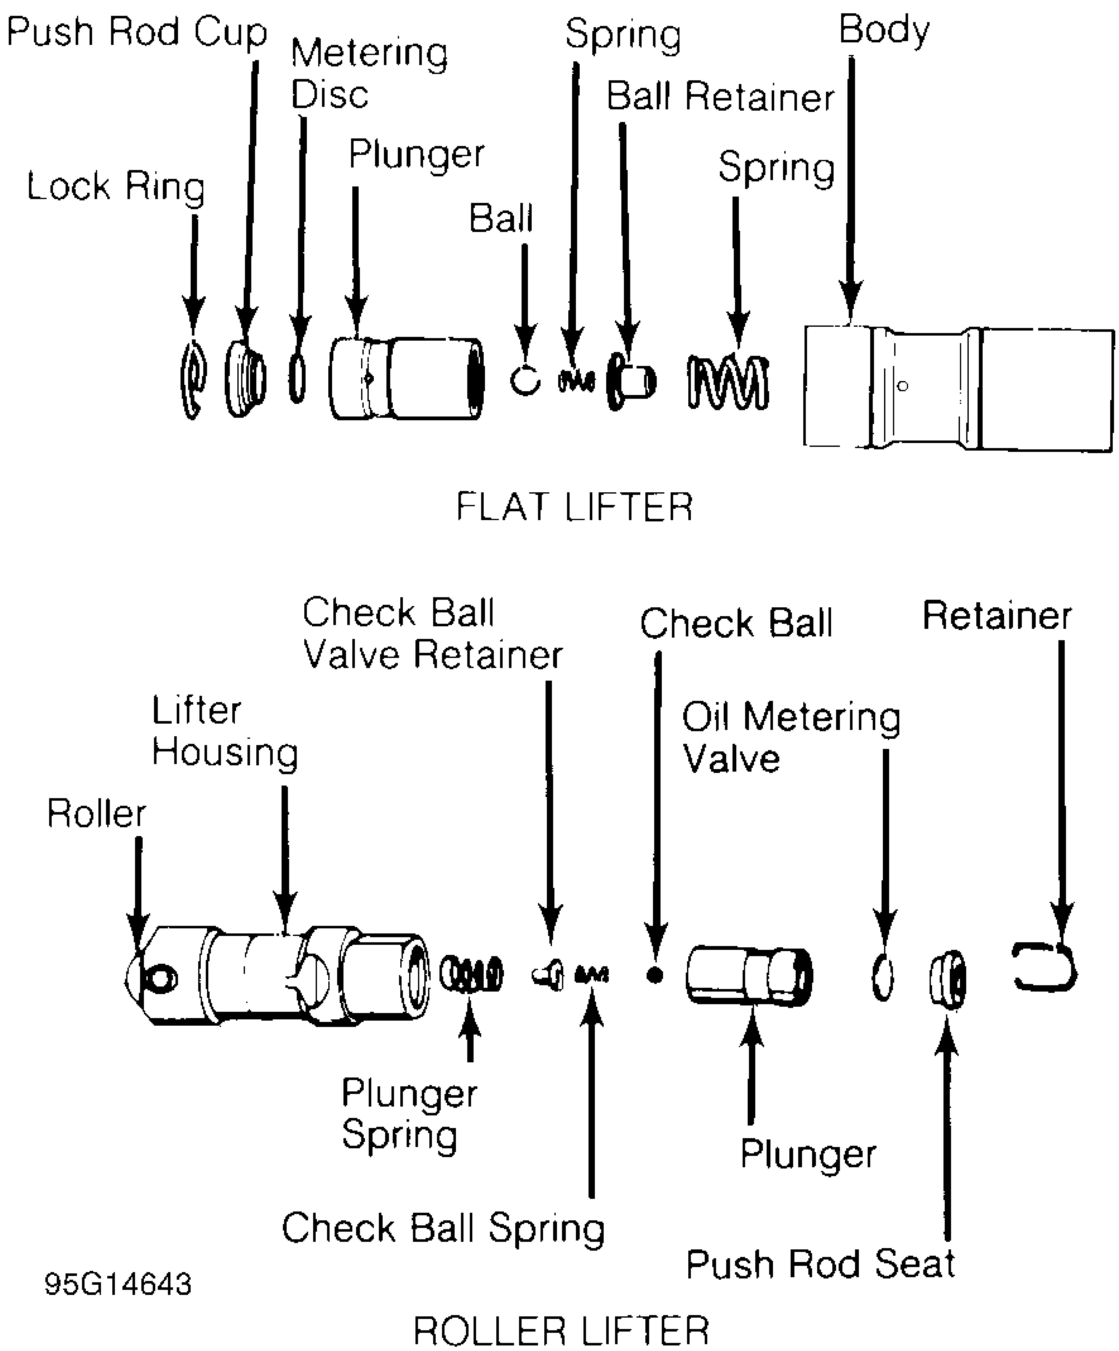

Fig. 13: Typical Hydraulic Valve Lifter Assemblies

Mechanical Lifters

Lifter assemblies must be installed in original locations. Remove rocker arm assembly and push rod. Mark components for location. Some applications require intake manifold or lifter cover removal. Remove lifter retainer plate (if used). To remove lifters, use lifter remover or magnet.

Inspect push rod contact area and lifter body for scoring or signs of wear. If body is scored, inspect lifter bore

for damage and lack of lubrication. Note amount of wear in lifter body-to-camshaft contact area. Surface must have smooth and convex contact face. If wear is apparent, carefully inspect cam lobe.

Coat lifter base, roller (if equipped) and lifter body with ample amount of Molykote or camshaft lubricant. Install lifter in original location. Install remaining components. Tighten bolts to specification. Adjust valves. See **VALVE ADJUSTMENT**.

Ridge in cylinder wall must be removed prior to piston removal. Failure to remove ridge prior to removing pistons will cause piston damage in piston ring lands or grooves.

With piston at bottom dead center, place rag in bore to trap metal chips. Install ridge reamer in cylinder bore. Adjust ridge reamer using manufacturer's instructions. Remove ridge using ridge reamer. DO NOT remove an excessive amount of material. Ensure ridge is completely removed.

PISTON & CONNECTING ROD REMOVAL

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Note top of piston. Some pistons may contain a notch, arrow or be marked FRONT. Piston must be installed in

proper direction to prevent damage with valve operation.

Check that connecting rod and cap are numbered for cylinder location and which side of cylinder block the number faces. Proper cap and connecting rod must be installed together. Connecting rod cap must be installed on connecting rod in proper direction to ensure bearing lock procedure. Mark connecting rod and cap if necessary. Pistons must be installed in original location.

Remove cap retaining nuts or bolts. Remove bearing cap. Install tubing protectors on connecting rod bolts. This protects cylinder walls from scoring during removal. Ensure proper removal of ridge. Push piston and connecting rod from cylinder. Connecting rod boss can be tapped with a wooden dowel or hammer handle to aid in removal.

Disassembly

Using ring expander, remove piston rings. Remove piston pin retaining rings (if equipped). Note direction of piston installation on connecting rod. On pressed type piston pins, special fixtures and procedures according to manufacturer must be used to remove piston pins. Follow manufacturer's recommendations to avoid piston distortion or breakage.

Cleaning

Remove all carbon and varnish from piston. Pistons and connecting rods may be cleaned in cold type chemical tank. Using ring groove cleaner, clean all deposits from ring grooves. Ensure all deposits are cleaned from ring grooves to prevent ring breakage or sticking. DO NOT attempt to clean pistons with wire brush.

Inspection

Inspect pistons for nicks, scoring, cracks or damage in ring areas. Connecting rod should be checked for cracks using Magnaflux procedure. Piston diameter must be measured in manufacturer's specified area.

Using telescopic gauge and micrometer, measure piston pin bore of piston in 2 areas, 90 degrees apart. This is done to check diameter and out-of-round.

Install proper bearing cap on connecting rod. Ensure bearing cap is installed in proper location. Tighten bolts or nuts to specification. Using inside micrometer, measure inside diameter in 2 areas, 90 degrees apart.

Connecting rod I.D. and out-of-round must be within specification. Measure piston pin bore I.D. and piston pin O.D. All components must be within specification. Subtract piston pin diameter from piston pin bore in piston and connecting rod to determine proper fit.

Connecting rod length must be measured from center of crankshaft journal inside diameter to center of piston pin bushing using proper caliper. Connecting rods must be the same length. Connecting rods should be checked on an alignment fixture for bent or twisted condition. Replace all components which are damaged or not within specification.

PISTON & CYLINDER BORE FIT

Ensure cylinder is checked for taper, out-of-round and properly honed prior to checking piston and cylinder bore fit. See **CYLINDER BLOCK**. Using dial bore gauge, measure cylinder bore.

Measure piston skirt diameter at 90 degree angle to piston pin at specified area by manufacturer. Subtract piston diameter from cylinder bore diameter to determine piston-to-cylinder clearance. Clearance must be within specification. Mark piston for proper cylinder location.

Install piston on connecting rod for corresponding cylinder. Ensure reference marking on top of piston corresponds with connecting rod and cap number. See **Fig. 14**.

Lubricate piston pin and install in connecting rod. Ensure piston pin retainers are fully seated (if equipped). On pressed type piston pins, follow manufacturer's recommended procedure to avoid distortion or breakage.

CHECKING PISTON RING CLEARANCES

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Piston rings must be checked for side clearance and end gap. To check end gap, install piston ring in cylinder in which it is to be installed. Using an inverted piston, push ring to bottom of cylinder in smallest cylinder diameter.

Using feeler gauge, check ring end gap. See **Fig. 15**. Piston ring end gap must be within specification. Ring breakage will occur if insufficient ring end gap exists.

Some manufacturers permit correcting insufficient ring end gap by using a fine file while other manufacturers

..

recommend using another ring set. Mark rings for proper cylinder installation after checking end gap.

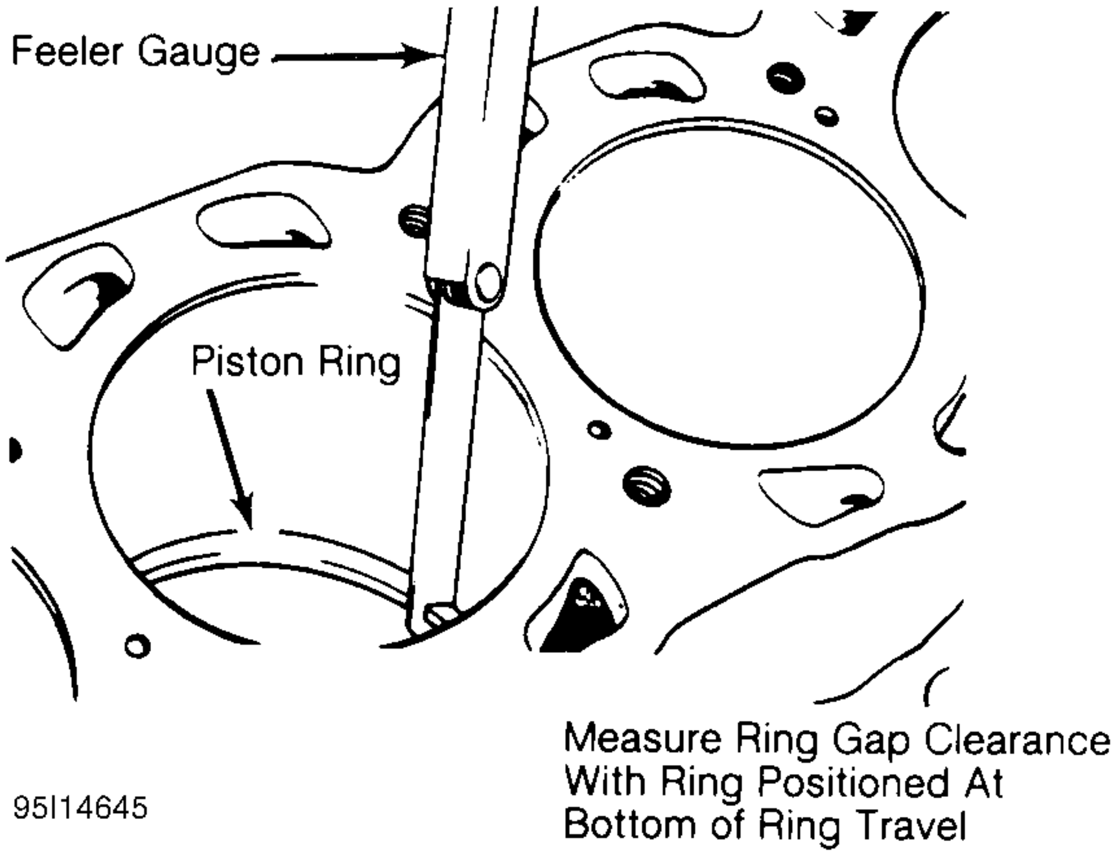

Fig. 15: Checking Piston Ring End Gap

For checking side clearance, install rings on piston. Using feeler gauge, measure clearance between piston ring and piston ring land. Check side clearance in several areas around piston. Side clearance must be within specification.

If side clearance is excessive, piston ring grooves can be machined to accept oversize piston rings (if available). Normal practice is to replace piston.

PISTON & CONNECTING ROD INSTALLATION

Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Cylinders must be honed prior to piston installation. See **CYLINDER HONING** under CYLINDER BLOCK.

Install upper connecting rod bearings. Lubricate upper bearings with engine oil. Install lower bearings in rod caps. Ensure bearing tabs are properly seated. Position piston ring gaps according to manufacturer's recommendations. See **Fig. 16**. Lubricate pistons, rings and cylinder walls.

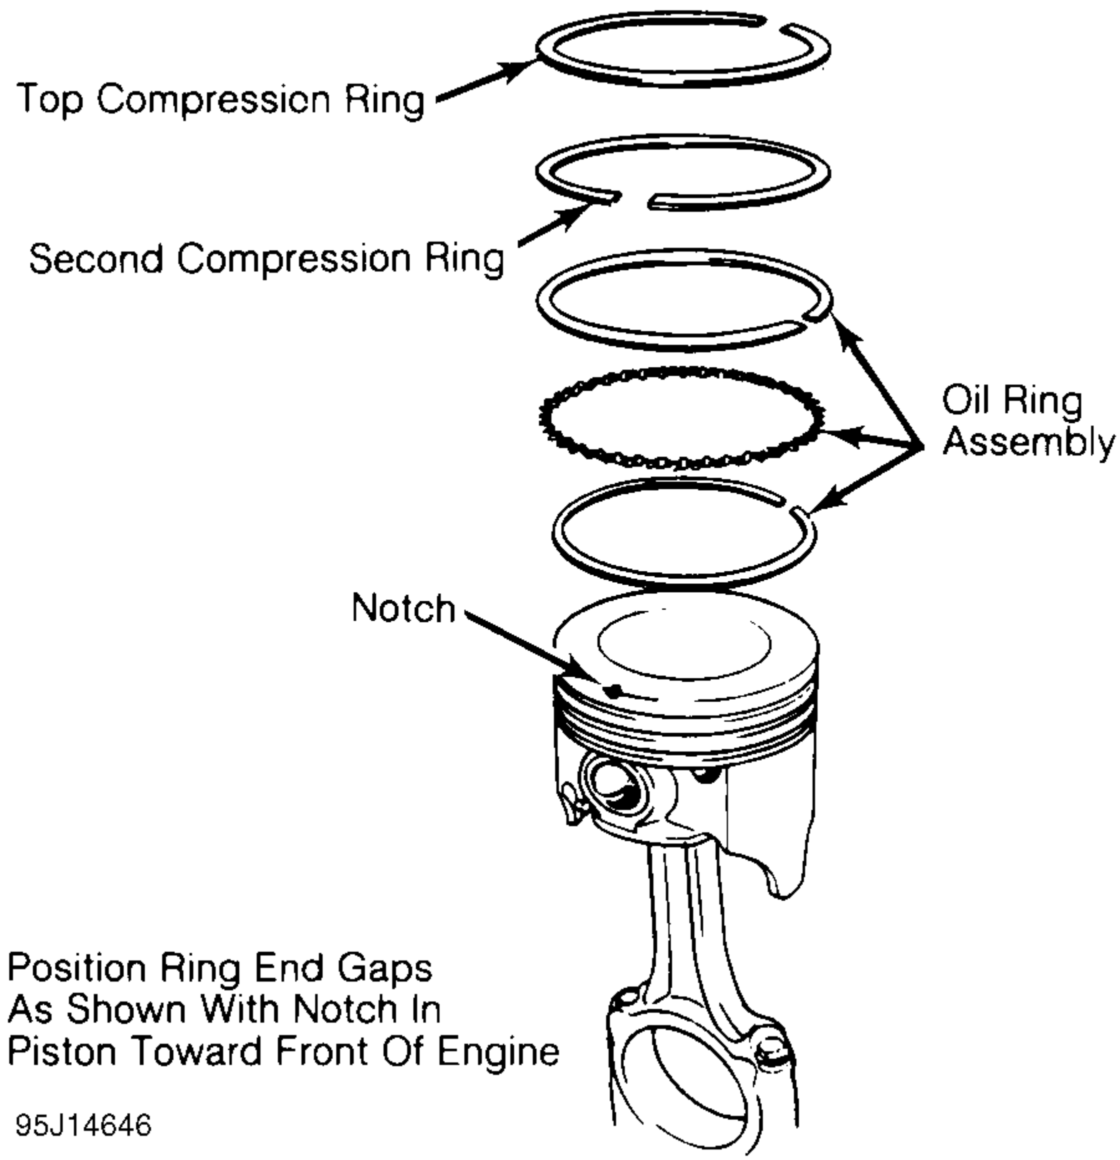

Fig. 16: Positioning Typical Piston Ring End Gap

Install ring compressor. Use care not to rotate piston rings. Compress rings with ring compressor. Install plastic tubing protectors over connecting rod bolts. Install piston and connecting rod assembly. Ensure piston notch, arrow or FRONT mark is toward front of engine. See **Fig. 17**.

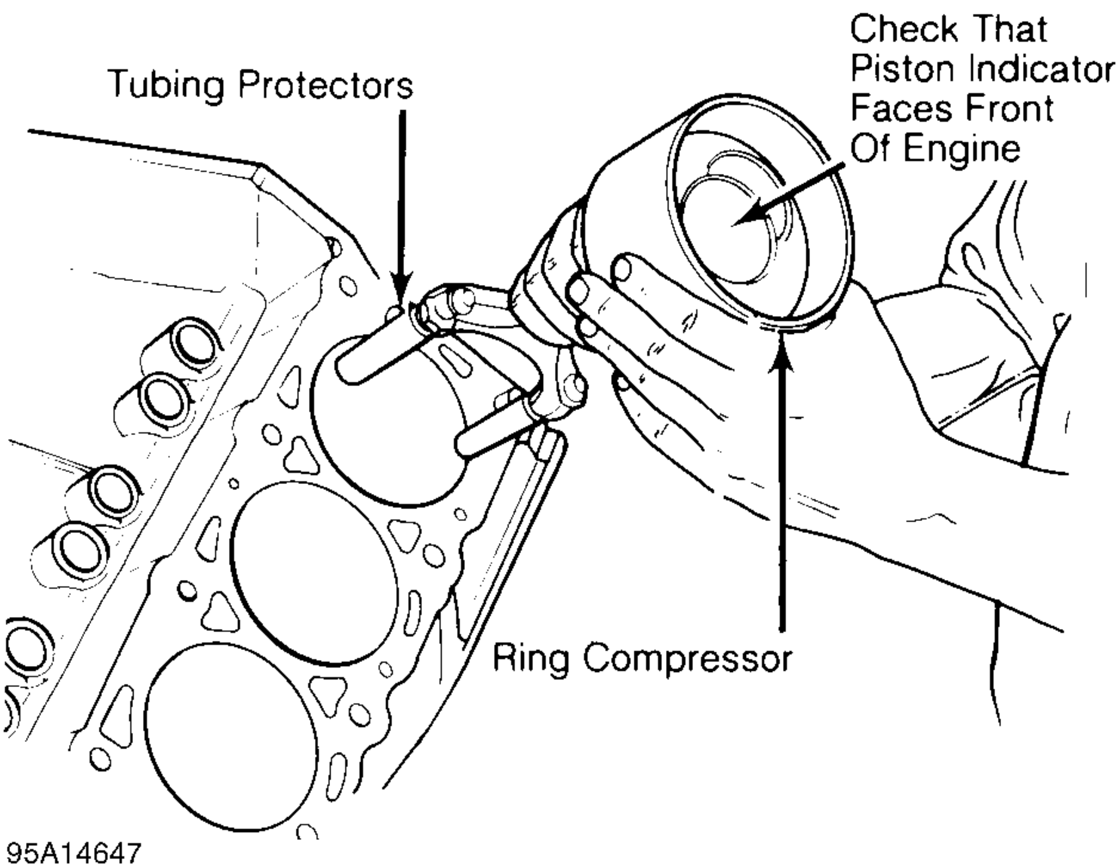

Fig. 17: Installing Piston & Connecting Rod Assembly

Carefully tap piston into cylinder until rod bearing is seated on crankshaft journal. Remove protectors. Install rod cap and bearing. Lightly tighten connecting rod bolts. Repeat procedure for remaining cylinders. Check bearing clearance. See **MAIN & CONNECTING ROD BEARING CLEARANCE**.

Once clearance is checked, lubricate journals and bearings. Install bearing caps. Ensure marks are aligned on connecting rod and cap. Tighten rod nuts or bolts to specification. Ensure rod moves freely on crankshaft. Check connecting rod side clearance. See **CONNECTING ROD SIDE CLEARANCE**.

CONNECTING ROD SIDE CLEARANCE

Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Position connecting rod toward one side of crankshaft as far as possible. Using feeler gauge, measure clearance

between side of connecting rod and crankshaft. See **Fig. 18**. Clearance must be within specification.

Check for improper bearing installation, wrong bearing cap or insufficient bearing clearance if side clearance is insufficient. Connecting rod may require machining to obtain proper clearance. Excessive clearance usually indicates excessive wear at crankshaft. Crankshaft must be repaired or replaced.

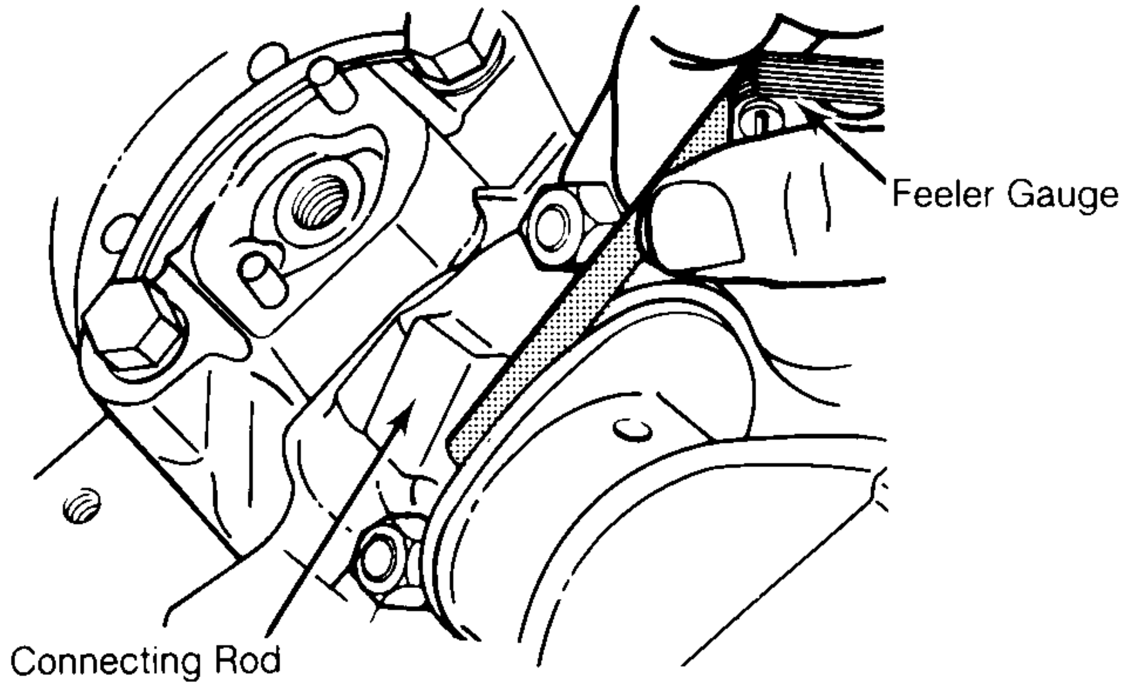

Fig. 18: Measuring Connecting Rod Side Clearance

MAIN & CONNECTING ROD BEARING CLEARANCE

Plastigage Method

Plastigage method may be used to determine bearing clearance. Plastigage can be used with an engine in service or during reassembly. Plastigage material is oil soluble.

Ensure journals and bearings are free of oil or solvent. Oil or solvent will dissolve material and false reading will be obtained. Install small piece of Plastigage along full length of bearing journal. Install bearing cap in

original location. Tighten bolts to specification.

CAUTION: DO NOT rotate crankshaft while Plastigage is installed. Bearing clearance will not be obtained if crankshaft is rotated.

Remove bearing cap. Compare Plastigage width with scale on Plastigage container to determine bearing clearance. See **Fig. 19**. Rotate crankshaft 90 degrees. Repeat procedure. This is done to check journal eccentricity. This procedure can be used to check oil clearance on both connecting rod and main bearings.

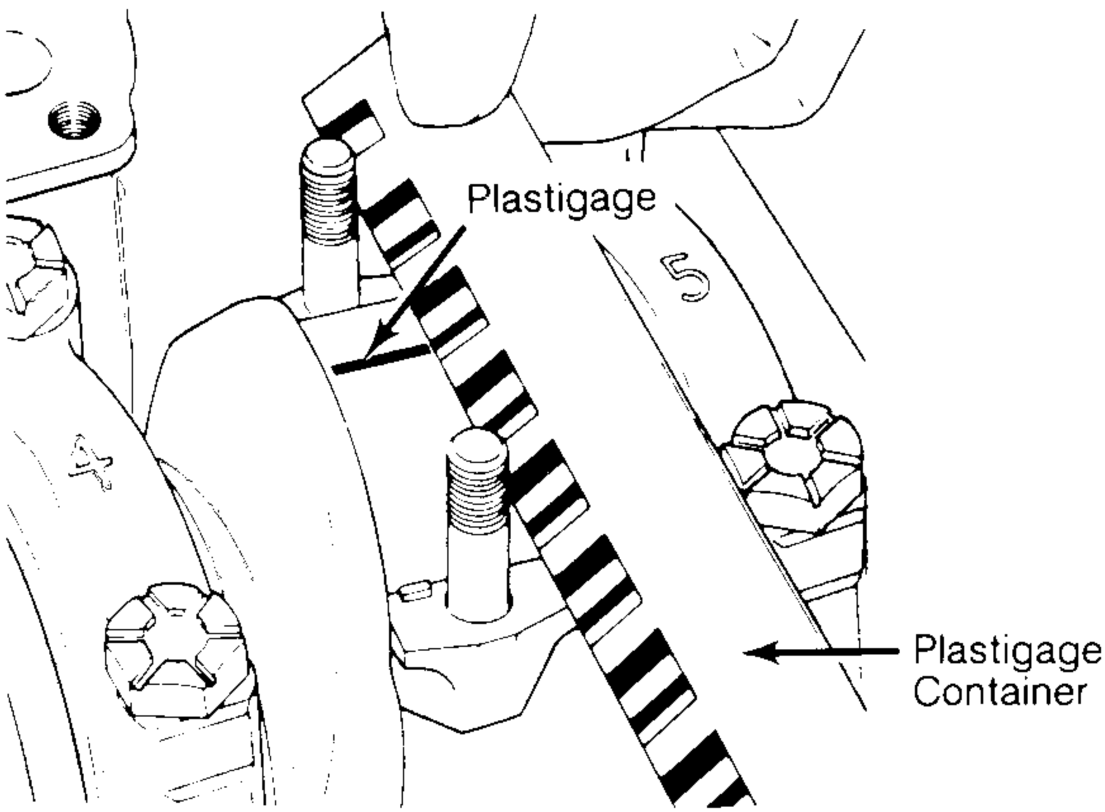

Fig. 19: Measuring Bearing Clearance

Micrometer & Telescopic Gauge Method

A micrometer is used to determine journal diameter, taper and out-of-round dimensions of the crankshaft. See **CLEANING & INSPECTION** under CRANKSHAFT & MAIN BEARINGS in this article.

With crankshaft removed, install bearings and caps in original location on cylinder block. Tighten bolts to specification. On connecting rods, install bearings and caps on connecting rods. Install proper connecting rod cap on corresponding rod. Ensure bearing cap is installed in original location. Tighten bolts to specification.

Using a telescopic gauge and micrometer or inside micrometer, measure inside diameter of connecting rod and main bearings bores. Subtract each crankshaft journal diameter from the corresponding inside bearing bore

diameter. This is the bearing clearance.

Thoroughly clean crankshaft using solvent. Dry with compressed air. Ensure all oil passages are clear and free of sludge, rust, dirt and metal chips.

Inspect crankshaft for scoring and nicks. Inspect crankshaft for cracks using Magnaflux procedure. Inspect rear seal area for grooving or damage. Inspect bolt hole threads for damage. If pilot bearing or bushing is used, check pilot bearing or bushing fit in crankshaft. Inspect crankshaft gear for damaged or cracked teeth. Replace gear if damaged. Ensure oil passage plugs are tight (if equipped).

Using micrometer, measure all journals in 4 areas to determine journal taper, out-of-round and undersize. See **Fig. 20**. Some crankshafts can be reground to the next largest undersize, depending on the amount of wear or damage. Crankshafts with rolled fillet cannot be reground and must be replaced.

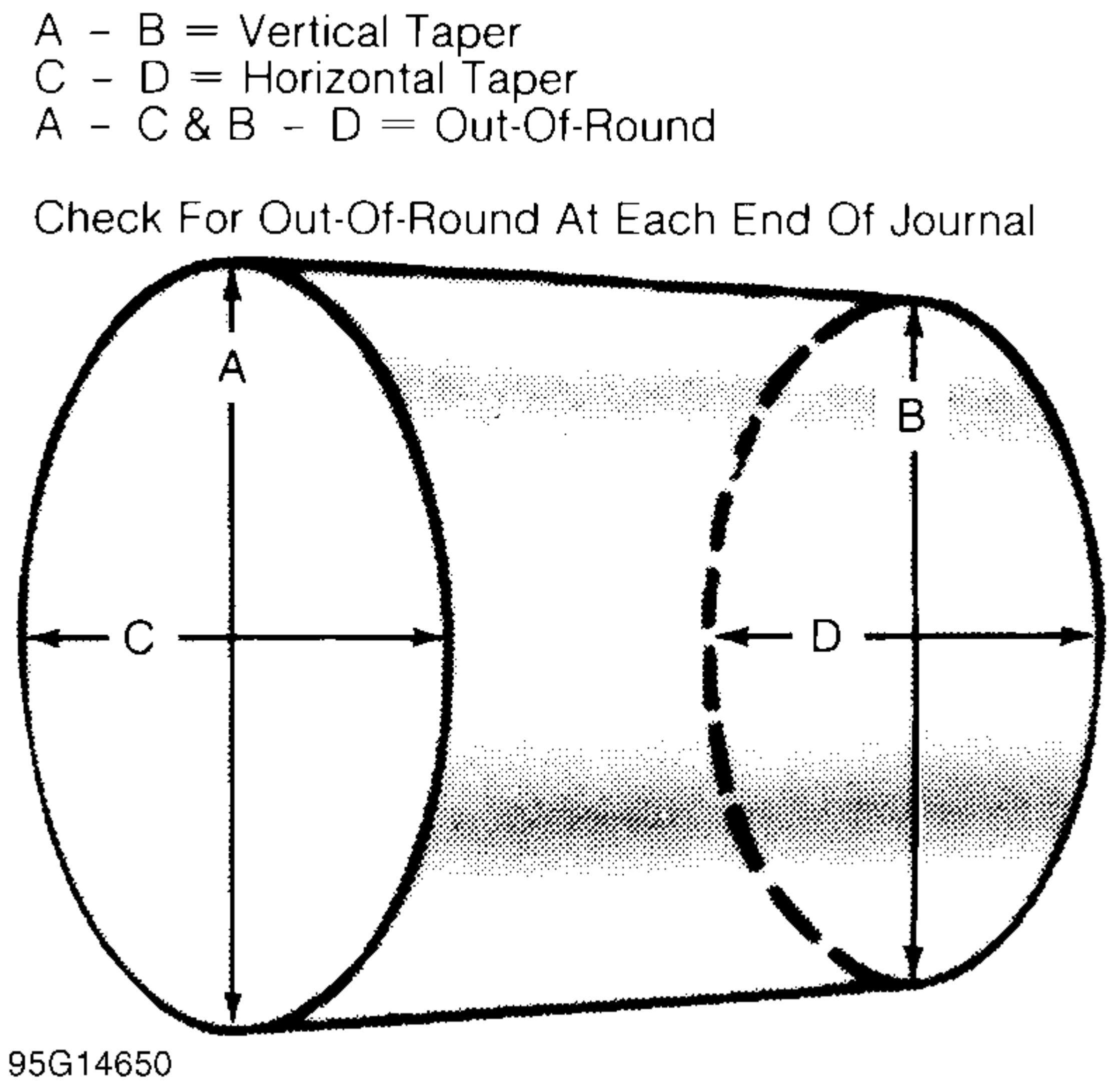

Fig. 20: Measuring Crankshaft Journals

Crankshaft journal runout should be checked. Install crankshaft in "V" blocks or bench center. Position dial indicator with tip resting on the main bearing journal area. See **Fig. 21**. Rotate crankshaft and note reading. Journal runout must not exceed specification. Repeat procedure on all main bearing journals. Crankshaft must be replaced if runout exceeds specification.

INSTALLATION

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Install upper main bearing in cylinder block. Ensure lock tab is properly located in cylinder block. Install bearings in main bearing caps. Ensure all oil passages are aligned. Install rear seal (if removed).

Ensure crankshaft journals are clean. Lubricate upper main bearings with clean engine oil. Carefully install crankshaft. Check each main bearing clearance using Plastigage method. See **MAIN & CONNECTING ROD BEARING CLEARANCE**.

Once clearance is checked, lubricate lower main bearing and journals. Install main bearing caps in original location. Install rear seal in rear main bearing cap (if removed). Some rear main bearing caps require sealant to be applied in corners to prevent oil leakage.

Install and tighten all bolts except thrust bearing cap to specification. Tighten thrust bearing cap bolts finger tight only. Some models require that thrust bearing be aligned. On most applications, crankshaft must be moved rearward then forward. Procedure may vary with manufacturer. Thrust bearing cap is then tightened to specification. Ensure crankshaft rotates freely. Crankshaft end play should be checked. See **CRANKSHAFT END PLAY**.

CRANKSHAFT END PLAY

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

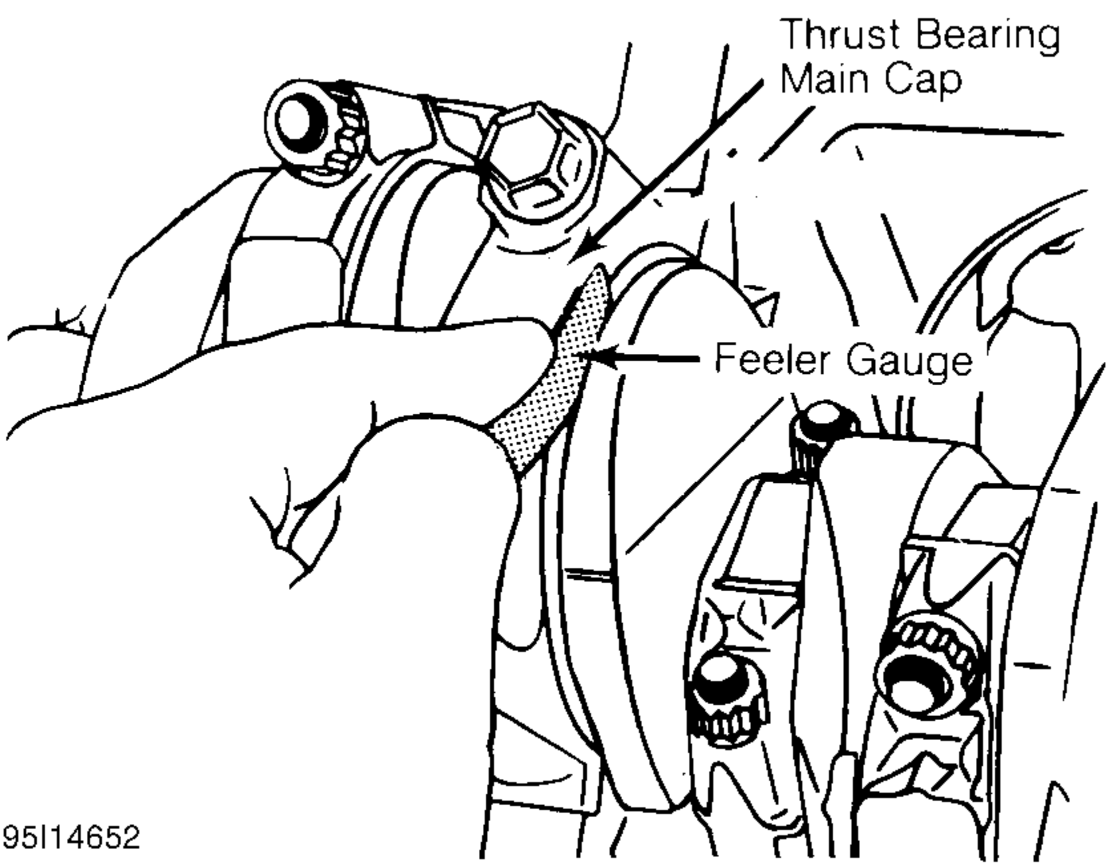
Dial Indicator Method

Crankshaft end play can be checked using dial indicator. Mount dial indicator on rear of cylinder block. Position dial indicator tip against rear of crankshaft. Ensure tip is resting against flat surface.

Pry crankshaft rearward. Adjust dial indicator to zero. Pry crankshaft forward and note reading. Crankshaft end play must be within specification. If end play is not within specification, check for faulty thrust bearing installation or worn crankshaft. Some applications offer oversize thrust bearings.

Feeler Gauge Method

Crankshaft end play can be checked using feeler gauge. Pry crankshaft rearward. Pry crankshaft forward. Using feeler gauge, measure clearance between crankshaft and thrust bearing surface. See **Fig. 22**.



95I14652

[Fig. 22: Checking Crankshaft End Play]

Crankshaft end play must be within specification. If end play is not within specification, check for faulty thrust bearing installation or worn crankshaft. Some applications offer oversize thrust bearings.

CYLINDER BLOCK

NOTE: **Examples used in this article are general in nature and do not necessarily relate to a specific engine or system. Illustrations and procedures have been chosen to guide mechanic through engine overhaul process. Descriptions of processes of cleaning, inspection, assembly and machine shop practice are included.**

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Block Cleaning

Only cast cylinder blocks should be hot tank cleaned. Aluminum cylinder blocks should be cleaned using cold tank method. Cylinder block is cleaned in order to remove carbon deposits, gasket residue and water jacket scale. Remove oil gallery plugs, freeze plugs and cam bearings before cleaning block.

Block Inspection

Visually inspect the block. Check suspected areas for cracks using the Dye Penetrant inspection method. Block may be checked for cracks using the Magnaflux method.

Cracks are most commonly found at the bottom of cylinders, main bearing saddles, near expansion plugs and between cylinders and water jackets. Inspect lifter bores for damage. Inspect all head bolt holes for damaged threads. Threads should be cleaned using tap to ensure proper head bolt torque. Consult machine shop concerning possible welding and machining (if required).

Cylinder Bore Inspection

Inspect bore for scoring or roughness. Cylinder bore is dimensionally checked for out-of-round and taper using dial bore gauge. For determining out-of-round, measure cylinder parallel and perpendicular to the block center line. Difference in the 2 readings is the bore out-of-round. Cylinder bore must be checked at top, middle and bottom of piston travel area.

Bore taper is obtained by measuring bore at the top and bottom. If wear has exceeded allowable limits, block must be honed or bored to next available oversize piston dimension.

Cylinder Honing

Cylinder must be properly honed to allow new piston rings to properly seat. Cross-hatching at correct angle and depth is critical to lubrication of cylinder walls and pistons.

A flexible drive hone and power drill are commonly used. Drive hone must be lubricated during operation. Mix equal parts of kerosene and SAE 20W engine oil for lubrication.

Apply lubrication to cylinder wall. Operate cylinder hone from top to bottom of cylinder using even strokes to

produce 45 degree cross-hatch pattern on the cylinder wall. DO NOT allow cylinder hone to extend below cylinder during operation.

Recheck bore dimension after final honing. Wash cylinder wall with hot soapy water to remove abrasive particles. Blow dry with compressed air. Coat cleaned cylinder walls with lubricating oil.

Deck Warpage

Check deck for damage or warped gasket surface. Place a straightedge across gasket surface of the deck. Using feeler gauge, measure clearance at center of straightedge. Measure across width and length of cylinder block at several points.

If warpage exceeds specifications, deck must be resurfaced. If warpage exceeds manufacturer's maximum tolerance for material removal, replace block.

NOTE: **Some manufacturers recommend that a total amount of material (cylinder head and cylinder block) can only be removed before components must be replaced.**

Deck Height

Distance from crankshaft center line to block deck is called the deck height. Measure and record front and rear main journals of crankshaft. To compute this distance, install crankshaft and retain with center main bearing and cap only. Measure distance from crankshaft journal to block deck, parallel to cylinder center line.

Add one half of main bearing journal diameter to distance from crankshaft journal to block deck. This dimension should be checked at front and rear of cylinder block. Both readings should be the same.

If difference exceeds specification, cylinder block must be repaired or replaced. Deck height and warpage should be corrected at the same time.

Main Bearing Bore & Alignment

For checking main bearing bore, remove all bearings from cylinder block and main bearing caps. Install main bearing caps in original location. Tighten bolts to specification. Using inside micrometer, measure main bearing bore in 2 areas 90 degrees apart. Determine bore size and out-of-round. If diameter is not within specification, block must be align-bored.

For checking alignment, place a straightedge along center line of main bearing saddles. Check for clearance between straightedge and main bearing saddles. Block must be align-bored if clearance exists.

Expansion Plug Removal

Drill hole in center of expansion plug. Remove with screwdriver or punch. Use care not to damage sealing surface.

Expansion Plug Installation

Ensure sealing surface is free of burrs. Coat expansion plug with sealer. Using wooden dowel or pipe of slightly smaller diameter, install expansion plug. Ensure expansion plug is evenly located.

Oil Gallery Plug Removal

Remove threaded oil gallery plugs using appropriate wrench. Soft press-in plugs are removed by drilling into plug and installing a sheet metal screw. Remove plug with slide hammer or pliers.

Oil Gallery Plug Installation

Ensure threads or sealing surface is clean. Coat threaded oil gallery plugs with sealer and install. Replacement soft press-in plugs are installed with a hammer and drift.

Clean camshaft with solvent. Ensure all oil passages are clear. Inspect cam lobes and bearing journals for pitting, flaking or scoring. Using micrometer, measure bearing journal O.D.

Support camshaft at each end with "V" blocks. Position dial indicator with tip resting on center bearing journal. Rotate camshaft and note camshaft runout reading. If reading exceeds specification, replace camshaft.

Check cam lobe lift by measuring base circle of camshaft using micrometer. Measure again at 90-degree angle to tip of cam lobe. Cam lift can be determined by subtracting base circle diameter from tip of cam lobe measurement.

Different lift dimensions are given for intake and exhaust cam lobes. Reading must be within specification. Replace camshaft if cam lobes or bearing journals are not within specification.

Inspect camshaft gear for chipped, eroded or damaged teeth. Replace gear if damaged. On camshafts using thrust plate, measure distance between thrust plate and camshaft shoulder. Replace thrust plate if not within specification.

Removal & Installation

Remove camshaft rear plug. Camshaft bearing remover is assembled with shoulder resting against bearing to be removed according to manufacturer's instructions. Tighten puller nut until bearing is removed. Remove remaining bearings, leaving front and rear bearings until last. These bearings act as a guide for camshaft bearing remover.

To install new bearings, puller is rearranged to pull bearings toward the center of block. Ensure all lubrication passages of bearing are aligned with cylinder block. Coat new camshaft rear plug with sealant. Install camshaft rear plug. Ensure plug is even in cylinder block.

Lubricate bearing surfaces and cam lobes with ample amount of Molykote or camshaft lubricant. Carefully install camshaft. Use care not to damage bearing journals during installation. Install thrust plate retaining bolts (if equipped). Tighten bolts to specification. On overhead camshafts, install bearing caps in original location. Tighten bolts to specification. On all applications, check camshaft end play.

Using dial indicator, check camshaft end play. Position dial indicator on front of engine block or cylinder head. Position indicator tip against camshaft. Push camshaft toward rear of cylinder head or engine and adjust indicator to zero.

Move camshaft forward and note reading. Camshaft end play must be within specification. End play may be adjusted by relocating gear, shimming thrust plate or replacing thrust plate depending on each manufacturer.

Timing chains will stretch during operation. Limits are placed upon amount of stretch before replacement is required. Timing chain stretch will alter ignition timing and valve timing.

To check timing chain stretch, rotate crankshaft to eliminate slack from one side of timing chain. Mark reference point on cylinder block. Rotate crankshaft in opposite direction to eliminate slack from remaining side of timing chain. Force other side of chain outward and measure distance between reference point and timing chain. See **Fig. 23**. Replace timing chain and gears if not within specification.

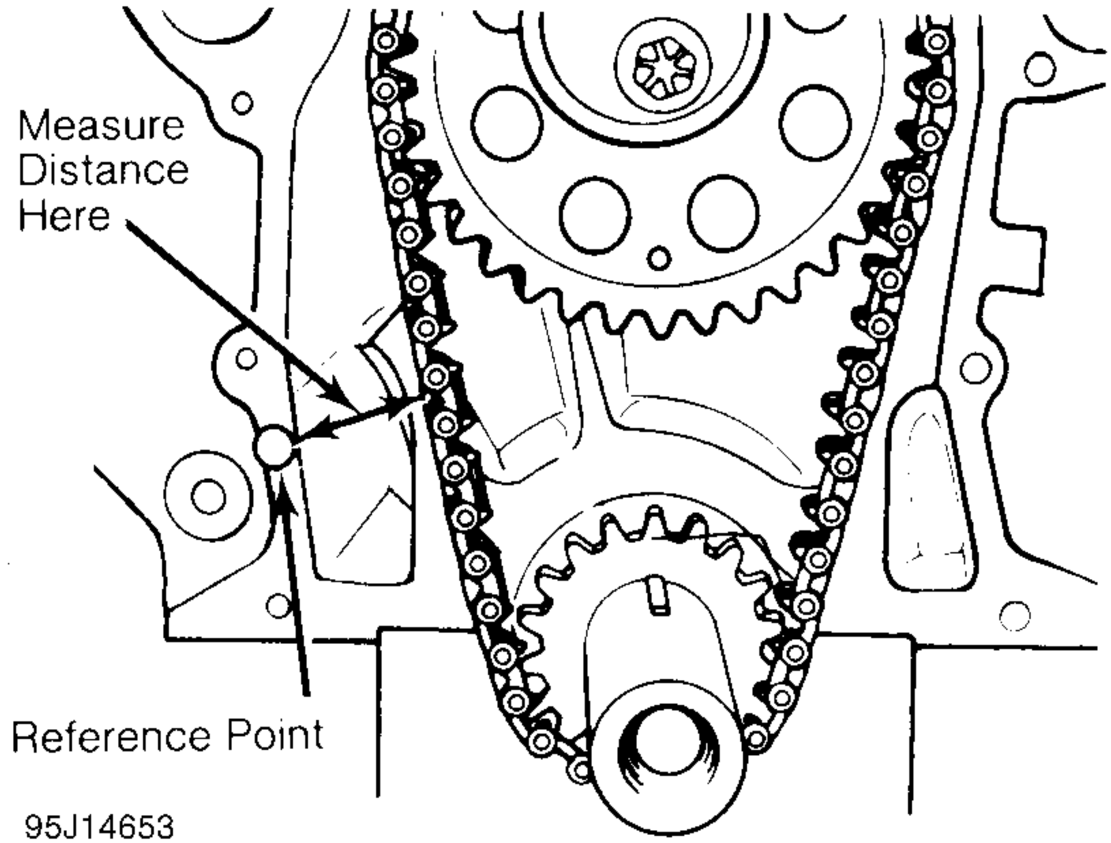

Fig. 23: Measuring Timing Chain Stretch

Timing chains must be installed so timing marks on camshaft gear and crankshaft gear are aligned according to manufacturer. See **Fig. 24**.

Cogged tooth belts are commonly used on overhead cam engines. Inspect belt teeth for rounded corners or cracking. Replace belt if it is cracked, damaged, missing teeth or oil soaked.

Used timing belt must be installed in original direction of rotation. Inspect all sprocket teeth for wear. Replace all worn sprockets. Sprockets are marked for timing purposes. Engine is positioned so that crankshaft sprocket mark will be upward. Camshaft sprocket is aligned with reference mark on cylinder head or timing belt cover and then timing belt can be installed. See **Fig. 25**.

If guide rails are used with spring loaded tensioners, ensure at least half of original rail thickness remains.

Spring loaded tensioner should be inspected for damage.

Ensure all timing marks are aligned. Adjust belt tension using manufacturer's recommendations. Belt tension may require checking using tension gauge. See **Fig. 26**.

On engines where camshaft gear operates directly on crankshaft gear, gear backlash and runout must be checked. To check backlash, install dial indicator with tip resting on tooth of camshaft gear. Rotate camshaft gear as far as possible. Adjust indicator to zero. Rotate camshaft gear in opposite direction as far as possible and note reading.

To determine timing gear runout, mount dial indicator with tip resting on face edge of camshaft gear. Adjust indicator to zero. Rotate camshaft gear 360 degrees and note reading. If backlash or runout exceeds specification, replace camshaft and/or crankshaft gear.

One-Piece Type Seal

For one-piece type oil seal installation, coat block contact surface of seal with sealer if seal is not factory coated. Ensure seal surface is free of burrs. Lubricate seal lip with engine oil and press seal into place using proper oil seal installer. See **Fig. 27**.

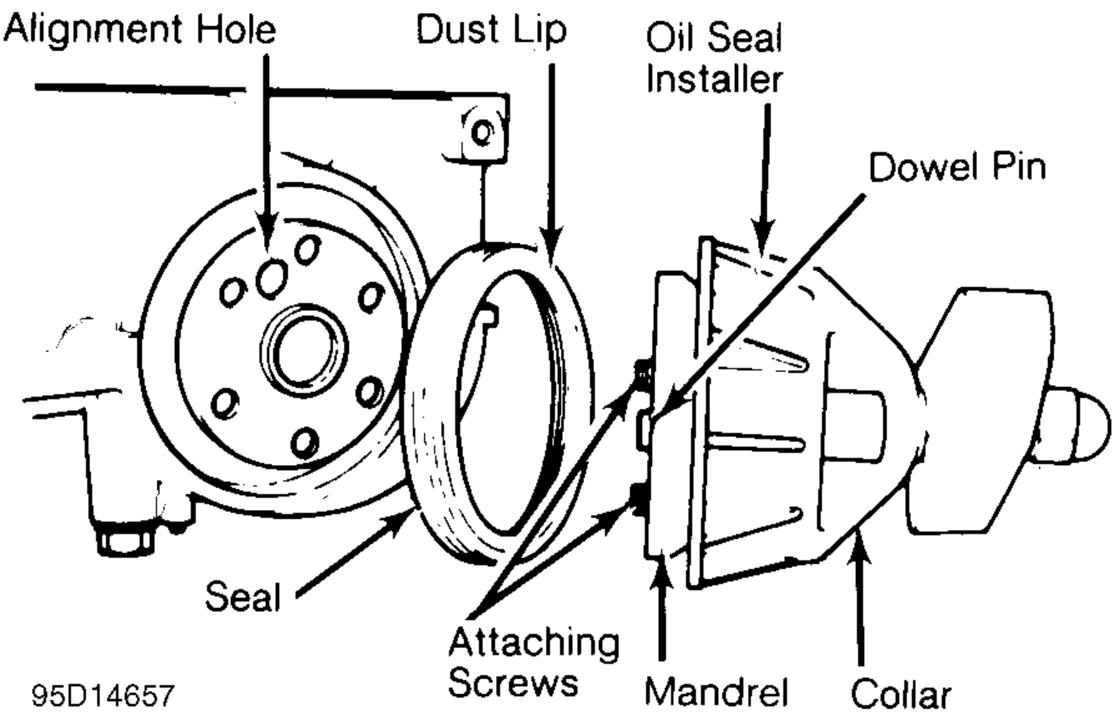

Fig. 27: Installing Typical One-Piece Oil Seal

Rope Type Seal

For rope type rear main oil seal installation, press seal lightly into seat area. Using seal installer, fully seat seal in bearing cap or cylinder block.

Trim seal ends even with cylinder block parting surface. Some applications require sealer to be applied on main bearing cap before installing. See **Fig. 28**.

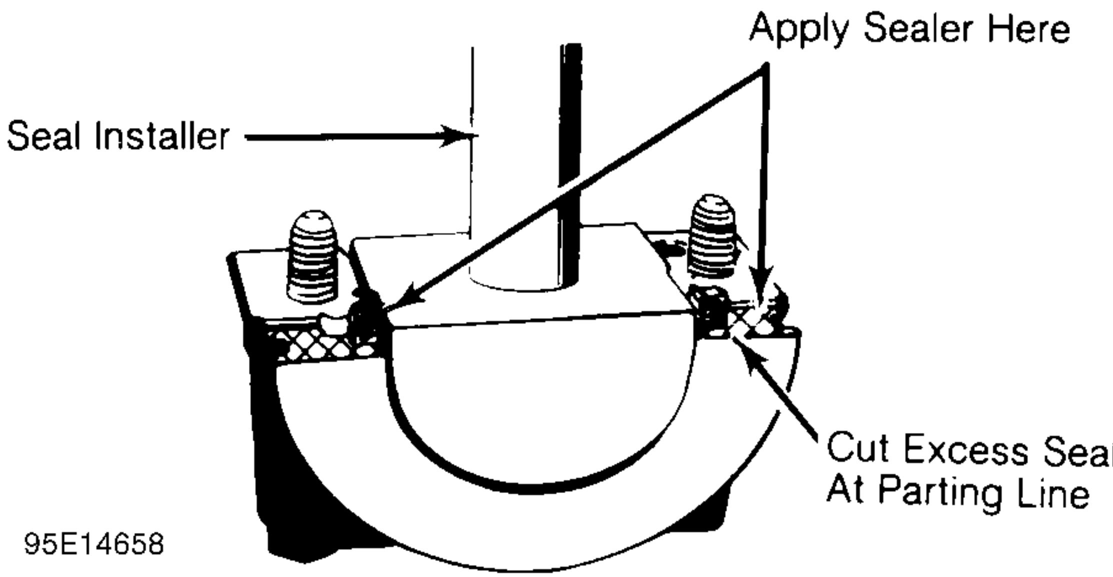

Fig. 28: Installing Typical Rope Seal

Split-Rubber Type Seal

Follow manufacturer's procedures when installing split-rubber type rear main oil seals. Installation procedures vary with manufacturer and engine type. See **Fig. 29**.

of cleaning, inspection, assembly and machine shop practice are included.

Always refer to appropriate engine overhaul article, if available, in the ENGINES section for complete overhaul procedures and specifications for the vehicle being repaired.

Pre-oil engine prior to operation to prevent engine damage. Lightly oiled oil pump will cavitate unless oil pump cavities are filled with engine oil or petroleum jelly.

Engine pre-oiling can be done using pressure oiler (if available). Connect pressure oiler to cylinder block oil passage such as oil pressure sending unit. Operate pressure oiler long enough to ensure correct amount of oil has filled crankcase. Check oil level while pre-oiling.

If pressure oiler is not available, disconnect ignition system. Remove oil pressure sending unit and replace with oil pressure test gauge. Using starter motor, rotate engine starter until gauge shows normal oil pressure for several seconds. DO NOT crank engine for more than 30 seconds to avoid starter motor damage. Ensure oil pressure has reached the most distant point from the oil pump.

NOTE: **If new lifters or camshaft are installed, some manufacturers require that a crankcase conditioner be added to engine oil. The engine should be operated for specified amount of time to aid in lifter break-in procedure.**

Piston rings require a break-in procedure to ensure seating of rings to cylinder walls. Serious damage may occur to rings if correct procedures are not followed.

Extremely high piston ring temperatures are obtained during break-in process. If rings are exposed to excessively high RPM or high cylinder pressures, ring damage can occur. Follow piston ring manufacturer's recommended break-in procedure.

FINAL ADJUSTMENTS

Check or adjust ignition timing and dwell (if applicable). Adjust valves (if necessary). Adjust idle speed and mixture. Retighten cylinder heads (if required). If cylinder head or block is aluminum, retighten bolts when engine is cold. Follow the engine manufacturer's recommended break-in procedure and maintenance schedule for new engines.

NOTE: **Some manufacturers require that head bolts be retightened after specified amount of operation. This must be done to prevent head gasket failure.**

Exhaust System - Challenger

DESCRIPTION

3.6L

WARNING: The normal operating temperature of the exhaust system is very high. Therefore, never work around or attempt to service any part of the exhaust system until it is cooled. Special care should be taken when working near the catalytic converter. The temperature of the converter rises to a high level after a short period of engine operation time.

CAUTION: Avoid application of rust prevention compounds or undercoating materials to exhaust system floor pan heat shields. Light overspray near the edges is permitted. Application of coating will result in excessive floor pan temperatures and objectionable fumes.

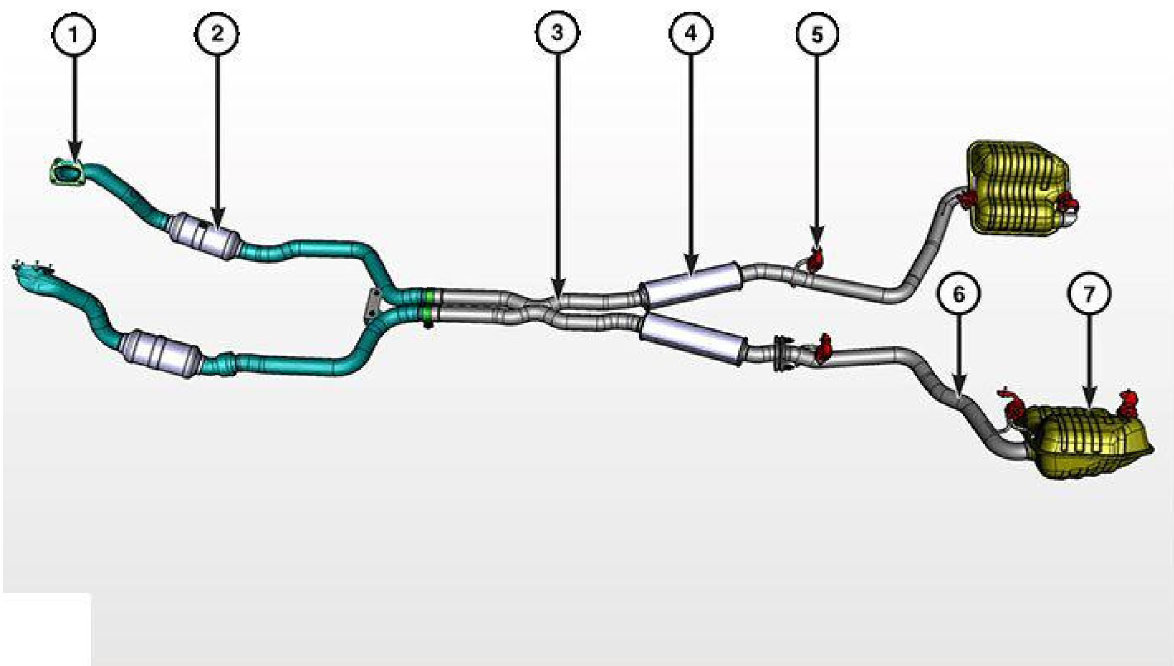

Fig. 1: Exhaust System - 3.6L
Courtesy of CHRYSLER GROUP, LLC

The 3.6L converters are mounted using a flange (1) to an integrated exhaust manifold. Refer to **DESCRIPTION** .

The system uses two catalytic converters (2) located in the front exhaust pipes, dual mufflers (4), with a dual tailpipe/resonator assembly (3).

The left side resonator assembly (7) can be serviced separately from the muffler assembly.

The exhaust system must be properly aligned to prevent stress, leakage and body contact. If the system contacts any body panel, it may amplify objectionable noises originating from the engine or body.

When inspecting an exhaust system, critically inspect for cracked or loose joints, stripped screw or bolt threads, corrosion damage and worn, cracked or broken hangers/isolators (5). Replace all components that are badly corroded or damaged. DO NOT attempt to repair.

When replacement is required, use original equipment parts (or their equivalent). This will assure proper alignment and provide acceptable exhaust noise levels.

5.7L exhaust systems use two catalytic converters (1) located in the front exhaust pipes, and dual mufflers (2), a

muffler/resonator assembly (4), and dual tailpipes (5).

The left side resonator assembly (6) can be serviced separately from the muffler assembly.

The front exhaust pipe/catalytic converter assembly is a hydra-form thin wall air gap design. This design is used to reduce heat, noise and improve emissions. When replacement is required, use original equipment parts (or their equivalent).

The exhaust system must be properly aligned to prevent stress, leakage and body contact. If the system contacts any body panel, it may amplify objectionable noises originating from the engine or body.

The front exhaust pipe/catalytic converter assemblies (1, 2) are hydra-form thin wall air gap design. This design is used to reduce heat, noise and improve emissions. When replacement is required, use original equipment parts (or their equivalent).

On a 6.2L/6.4L, both catalytic converters attach directly to the exhaust manifold using studs and nuts.

The exhaust down pipes exit the converters and connect into the rear muffler and resonator assembly.

The SRT performance exhaust systems (4) use dual mufflers (3), dual resonator and tailpipes (1). Each exhaust bank contains an electronic active exhaust valve (2) located underneath the rear cradle.

The electronic active exhaust valves are comprised of two elements, an electronic actuator, which can be serviced separately and a mechanical valve, that is welded into the exhaust pipes and must be serviced with the exhaust assembly.

The exhaust system must be properly aligned to prevent stress, leakage and body contact. If the system contacts any body panel, it may amplify objectionable noises originating from the engine or body.

ADJUSTMENTS

ADJUSTMENTS

A misaligned exhaust system is usually indicated by a vibration, rattling noise, or binding of exhaust system components. These noises are sometimes hard to distinguish from other chassis noises. Inspect exhaust system for broken or loose clamps, heat shields, isolators, and brackets. Replace or tighten as necessary. It is important that exhaust system clearances and alignment be maintained.

Perform the following procedures to align the exhaust system:

1. Loosen clamps and support brackets.
2. Align the exhaust system starting at the front, working rearward.
3. Tighten all clamps and brackets once alignment and clearances are achieved.

INSPECTION

Inspect the exhaust pipes, catalytic converters, muffler, and resonators for cracked joints, broken welds and corrosion damage that would result in a leaking exhaust system. Inspect the clamps, support brackets, and insulators for cracks and corrosion damage.

NOTE: **Slip joint band clamps are spot/tack welded to exhaust system. If a band clamp must be replaced, the spot/tack weld must be ground off.**

VALVE, ACTIVE EXHAUST

DESCRIPTION

DESCRIPTION

The SRT performance exhaust systems use two electronic active exhaust valves located underneath the rear cradle, between the mufflers and resonators.

The electronic exhaust valves are actuated by the Powertrain Control Module (PCM) and have been calibrated to refine the tailpipe and cabin exhaust noise while mitigating exhaust drone.

The electronic active exhaust valves are comprised of two elements: The electronic actuator and the mechanical valve.

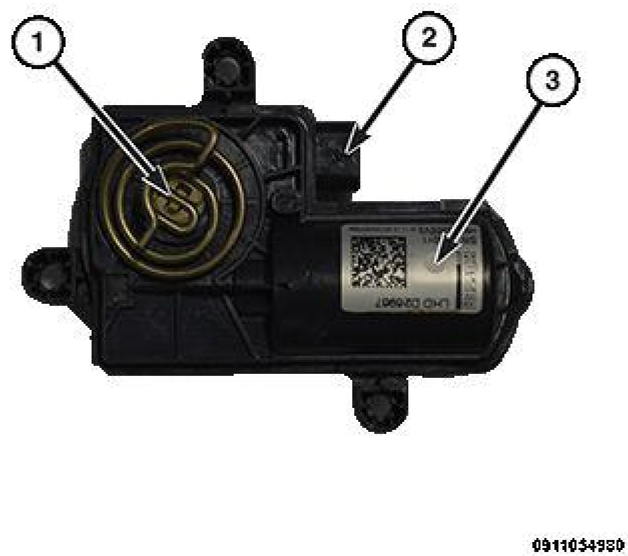

Fig. 5: Electronic Actuator Components
Courtesy of CHRYSLER GROUP, LLC

Each electronic actuator (3) has a transmission spring (1) and single wire harness connection (2) which connects to the vehicle harness above the rear cradle.

The electronic actuator can be serviced separately from the exhaust system.

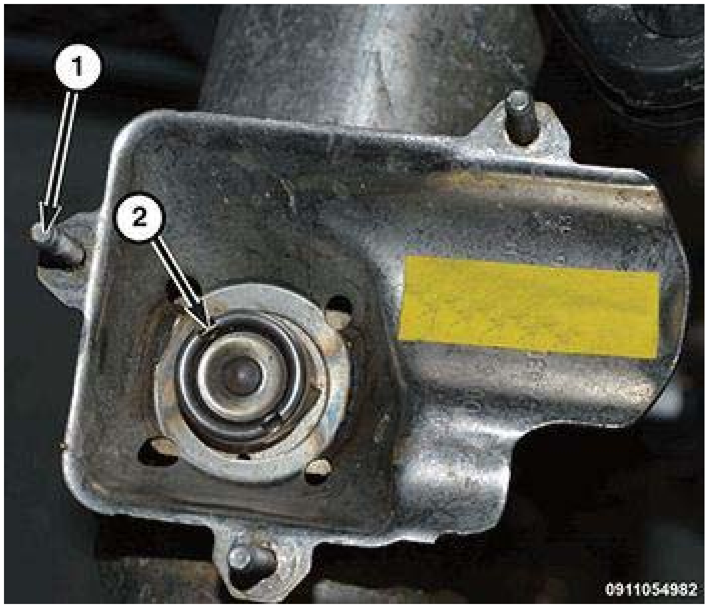

Fig. 6: Studs & Slots
Courtesy of CHRYSLER GROUP, LLC

Each mechanical valve is welded into the exhaust pipe and must be serviced with the exhaust assembly.

There are three studs (1) used to fasten the electronic actuator to the mechanical valve.

The mechanical valve contains slots (2) which must align with the electronic actuator transmission spring.

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING

The hard wired circuits may be diagnosed using conventional diagnostic tools and procedures. Refer to the appropriate wiring information. The wiring information includes wiring diagrams, details of wire harness routing and retention, connector pin out information and location views for the various wire harness connectors, splices and grounds.

However, conventional diagnostic methods will not prove conclusive in the diagnosis of the electronic active exhaust valve system or the electronic controls and communication between modules and other devices that provide some features of the system. The most reliable, efficient and accurate means to diagnose the system or the electronic controls and communication related to system operation requires the use of a diagnostic scan tool.

The electronic active exhaust valves will set an engine light if a problem is detected (i.e. stuck open or closed, become unplugged, etc.).

NOTE: **On vehicle key-on, the actuators will cycle from open to close to ensure they have the correct range of travel. If they are unattached from the valve body they will continue to cycle indefinitely and turn on an engine light after 7 seconds.**

REMOVAL

REMOVAL

1. Raise and support the vehicle. Refer to HOISTING, STANDARD PROCEDURE .

2. Disconnect the wire harness connector (2).
3. Remove the three electronic active exhaust valve retaining nuts (1).
4. Remove the electronic active exhaust valve from the exhaust pipe.

INSTALLATION

INSTALLATION

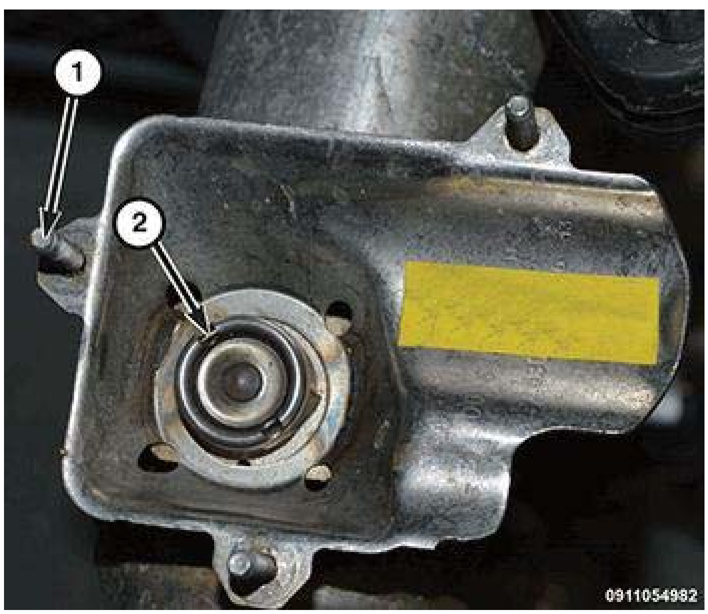

Fig. 8: Studs & Slots
Courtesy of CHRYSLER GROUP, LLC

NOTE: **Installing the actuator requires the actuator spring to be seated into the slots (2) on the exhaust valve axle rod.**

1. Position the electronic active exhaust valve onto the three mounting studs (1).
2. If the actuator spring cannot be seated into the exhaust valve axle rod slots (2), install the actuator bolts hand tight.
3. With vehicle in the run position, and the engine off, plug in the actuator. The actuator will cycle and seat into the slots, then turn off the vehicle. If this step is not completed successfully, the actuator will continue to cycle every minute and an engine code will be illuminated.

4. Tighten the retaining nuts (1) to the proper torque specification. Refer to **SPECIFICATIONS**.
5. Connect the wire harness connector (2) to the electronic active exhaust valve.
6. Remove support and lower the vehicle.

INSPECTION

INSPECTION

WARNING: **The normal operating temperature of the exhaust system is very high. Therefore, never attempt to service any part of the exhaust system until it is cooled. Special care should be taken when working near the catalytic converter. The temperature of the converter rises to a high level after a short period of engine operation time.**

Check the catalytic converter for a flow restriction. Exhaust System Restriction Check for procedure. Refer to **DIAGNOSIS AND TESTING**.

Visually inspect the catalytic converter element by using a borescope or equivalent. Remove oxygen sensor(s) and insert borescope. If borescope is not available, remove converter and inspect element using a flashlight. Inspect element for cracked or melted substrate.

NOTE: **Before replacing a catalytic converter, determine the root cause of failure. Most catalytic converter failures are caused by air, fuel or ignition problems. Refer to the appropriate diagnostic information for test procedures.**

FRAME

WARNING

USE OF HEAT DURING REPAIR

WARNING: Chrysler Group LLC engineering's position on the use of heat during collision repair is as follows:

- **Any body panel or frame component damaged which is to be repaired and reused, must be repaired using the "cold straightening" method. No heat may be used during the straightening process.**
- **During rough straightening prior to panel replacement, damaged panels or frame components may be heated to assist in body/frame realignment. The application of heat must be constrained to the parts which will be replaced and not allowed to affect any other components.**

This "no heat" recommendation is due to the extensive use of high strength and advanced high strength steels in Chrysler Group LLC products. High-strength materials can be substantially and negatively affected from heat input which will not be obviously known to the repairer or consumer.

Ignoring these recommendations may lead to serious compromises in the ability to protect occupants in a future collision event, reduce the engineered qualities and attributes, or decrease the durability and reliability of the vehicle.

This statement supersedes any previously released information by the Chrysler Group LLC.

Failure to follow these instructions may result in serious or fatal injury.

WARNINGS

WARNING: Use an Occupational Safety and Health Administration (OSHA) approved breathing filter, when spraying paint or solvents in a confined area. Failure to follow these instructions may result in possible serious or fatal injury.

- **avoid prolonged skin contact with petroleum or alcohol based cleaning solvents.**
- **do not stand under a hoisted vehicle that is not properly supported on safety stands. Failure to follow these instructions may result in possible serious or fatal injury.**

CAUTION: When holes are drilled or punched in an inner body panel, verify the depth of space to the outer body panel, electrical wiring or other components. Damage to the vehicle can result.

- do not weld exterior panels unless combustible material on the interior of vehicle is removed from the repair area. Fire or hazardous conditions, can result.
- always have a fire extinguisher ready for use when welding.
- disconnect the negative (-) cable clamp from the battery when servicing electrical components that are live when the ignition is off. Damage to electrical system can result.
- do not use abrasive chemicals or compounds on painted surfaces. Damage to finish can result.
- do not use harsh alkaline based cleaning solvents on painted or upholstered surfaces. Damage to finish or color can result.
- do not hammer or pound on plastic trim panel when servicing interior trim. Plastic panels can break.

RESTRAINT WARNINGS

WARNING: To avoid serious or fatal injury on vehicles equipped with the Supplemental Restraint System (SRS), never attempt to repair the electrically conductive circuits or wiring components related to the SRS for which there is no MOPAR wiring repair kit. It is important to use ONLY the recommended splicing kit and procedure. For applicable and available MOPAR wiring repair kits, please visit the MOPAR Connector Web Site at the following address on the internet: (http://dto.vftis.com/mopar/disclaimer.asp). Inappropriate repairs can compromise the conductivity and current carrying capacity of those critical electrical circuits, which may cause SRS components not to deploy when required, or to deploy when not required. Only minor cuts or abrasions of wire and terminal insulation where the conductive material has not been damaged, or connector insulators where the integrity of the latching and locking mechanisms have not been compromised may be repaired using appropriate methods.

WARNING: To avoid serious or fatal injury during and following any seat belt or child restraint anchor service, carefully inspect all seat belts, buckles, mounting hardware, retractors, tether straps, and anchors for proper installation, operation, or damage. Replace any belt that is cut, frayed, or torn. Straighten any belt that is twisted. Tighten any loose fasteners. Replace any belt that has a damaged or ineffective buckle or retractor. Replace any belt that has a bent or damaged latch plate or anchor plate. Replace any child restraint anchor or the unit to which the anchor is integral that has been bent or damaged. Never attempt to repair a seat belt or child restraint component. Always replace damaged or ineffective seat belt and child restraint components with the correct, new and unused replacement parts listed in the Chrysler MoparÃ® Parts Catalog. Failure to follow these instructions may result in possible

serious or fatal injury.

WARNING: To avoid serious or fatal injury on vehicles equipped with airbags, disable the Supplemental Restraint System (SRS). Refer to **RESTRAINTS - SERVICE INFORMATION** before attempting any steering wheel, steering column, airbag, Occupant Classification System (OCS), seat belt tensioner, impact sensor or instrument panel component diagnosis or service. Disconnect and isolate the battery negative (ground) cable, then wait two minutes for the system capacitor to discharge before performing further diagnosis or service. This is the only sure way to disable the SRS. Failure to follow these instructions may result in accidental airbag deployment.

WARNING: To avoid potential physical injury or damage to sensitive electronic circuits and systems, always disconnect and isolate the battery negative (ground) cable and the positive cable, then ground the positive cable to discharge the Occupant Restraint Controller (ORC) capacitor before performing any welding operations on the vehicle. Failure to take the proper precautions could result in accidental airbag deployment, possible damage to the Supplemental Restraint System (SRS) circuits and components, and possible damage to other electronic circuits and components. Whenever a welding process is being performed within 12 inches (30 centimeters) of an electronic module or wiring harness, then that module or harness should be relocated out of the way, or disconnected. Always protect against component or vehicle damage from weld spatter by using weld blankets and screens.

WARNING: To avoid serious or fatal injury, do not attempt to dismantle an airbag unit or tamper with its inflator. Do not puncture, incinerate or bring into contact with electricity. Do not store at temperatures exceeding 93Â° C (200Â° F). An airbag inflator unit may contain sodium azide and potassium nitrate. These materials are poisonous and extremely flammable. Contact with acid, water, or heavy metals may produce harmful and irritating gases (sodium hydroxide is formed in the presence of moisture) or combustible compounds. An airbag inflator unit may also contain a gas canister pressurized to over 17.24 kPa (2500 psi). Failure to follow these instructions may result in possible serious or fatal injury.

WARNING: To avoid serious or fatal injury when handling a seat belt tensioner retractor. Exercise proper care to keep fingers out from under the retractor cover and away from the seat belt webbing where it exits from the retractor cover. Failure to follow these instructions may result in possible serious or fatal injury.

WARNING: To avoid serious or fatal injury, replace all Supplemental Restraint System (SRS) components only with parts specified in the Chrysler MoparÂ® Parts Catalog. Substitute parts may appear interchangeable, but internal differences may result in inferior occupant protection.

WARNING: To avoid serious or fatal injury, the fasteners, screws, and bolts originally used for the Supplemental Restraint System (SRS) components must never be replaced with any substitutes. These fasteners have special coatings and are

specifically designed for the SRS. Anytime a new fastener is needed, replace it with the correct fasteners provided in the service package or specified in the Chrysler MoparÃ® Parts Catalog.

WARNING: **To avoid serious or fatal injury when a steering column has an airbag unit attached, never place the column on the floor or any other surface with the steering wheel or airbag unit face down. Failure to follow these instructions may result in possible serious or fatal injury.**

STANDARD PROCEDURE

REAR FRAME RAIL REPLACEMENT

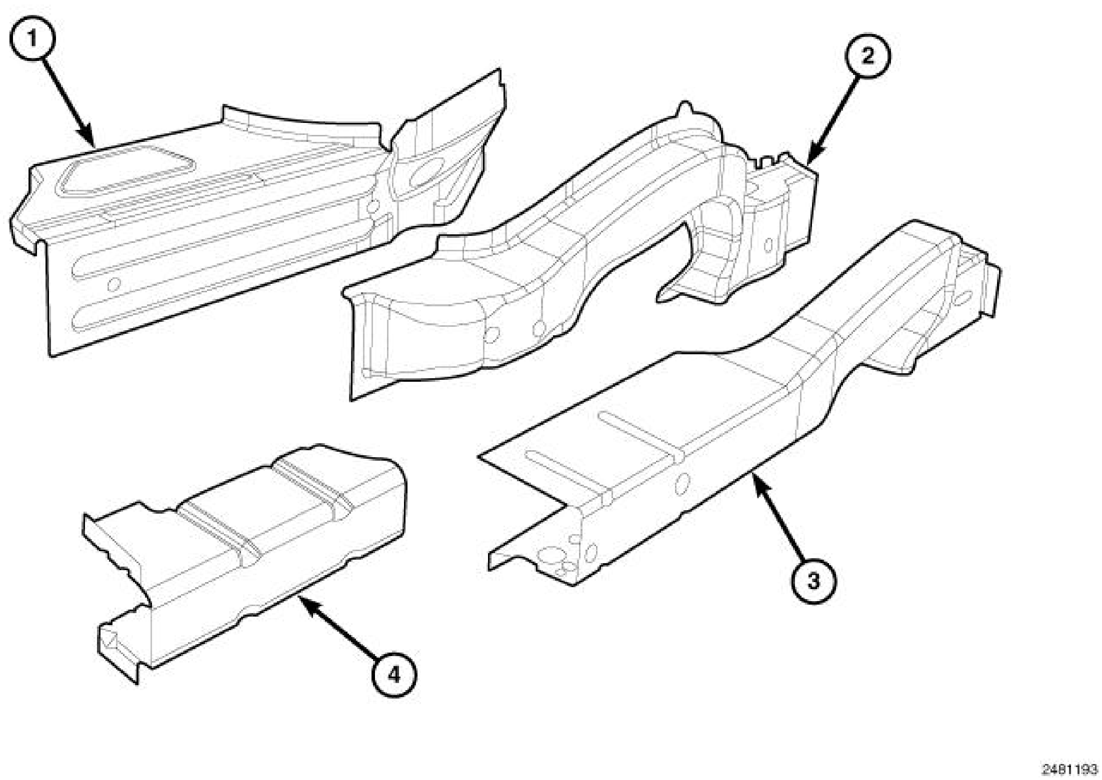

Fig. 41: Rear Frame Rail Replacement Components
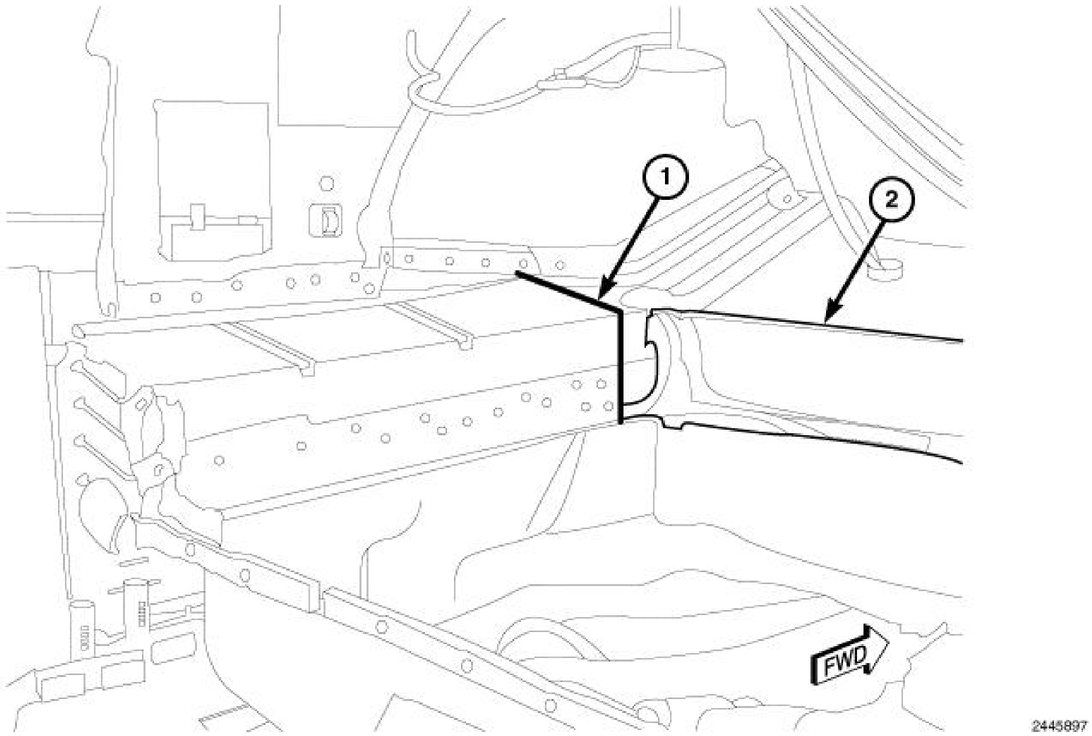
Courtesy of CHRYSLER GROUP, LLC

1 - COVER PLATE	
2 - RAIL, REAR, OUTER	
3 - RAIL, REAR, INNER	
4 - REINFORCEMENT, REAR RAIL INNER, REAR	

"Rail, rear, outer" (2) - this portion of the rear rail assembly is not visible as it is gloved inside the "rail, rear, inner" (3) and the "cover plate, rear rail extension" (1). **This rail may not be sectioned!**

"Reinforcement, rear rail inner rear" (4) - welded inside of the "rail, rear, inner" (3) and extends from the end of that rail to the "panel, deck opening lower".



[Fig. 42: Rear Inner Rail & Crossmember]
Courtesy of CHRYSLER GROUP, LLC

"Rail, rear inner" may be sectioned at this location (1), greatly reducing vehicle disruption and repair costs.

This partial replacement procedure presumes that all damage to the "rail, rear inner" is aft of the crossmember (2).

The following procedure details key points of the repair. I-CAR training is presumed, and should be followed for best-practice repair procedures.

1. Mount the damaged vehicle onto a structural straightening bench and check/correct any body misalignment utilizing three dimensional measuring equipment.
2. Remove all components in area of repair allowing unimpeded access for cutting and welding operations.
3. Trunk floor should be removed if being replaced, or the necessary welds released and the weld flange bent inboard to provide access to the rail for the butt-joint.
4. Using the round hole in the "Rail, Rear, Inner" as a point of reference, measure 125 mm (5 in.) forward for the left rail, or 150 mm (6 in.) forward for the right rail, and scribe a vertical line on the rail.
5. With the vertical line just made as reference, cut off the damaged "Rail, Rear, Inner" taking care not to damage the "Rail, Rear, Outer", using a reciprocating saw or cut-off wheel, and remove the damaged portion.
6. Utilize the same measuring and cutting process above to remove the replacement portion from the service part.
7. Using a surface conditioning disk, remove all e-coat within 25 mm (1 in.) of the cut location and de-bur the cut edge.
8. If the "Rail, Rear, Outer" was damaged during the cutting operation, MIG-weld the damage and dress the weld.

9. Fabricate 19 mm (0.75 in.) weld backers from the damaged component, or the remains of the service part, and tack in place on the replacement rail section at the butt-joint location.
10. Position and clamp the replacement rail and confirm proper position with measuring equipment.
11. Weld the service part in position using a skip-stitch process.
12. Complete remaining repairs in the damaged area.
13. Clean and dress all welded areas.
14. Apply epoxy primer to the exterior of the rail at the repair location.
15. Apply quality body sealer to all areas previously sealed to duplicate the original appearance. Note that additional sealer may be applied to better protect the exterior exposed seams from road spray.
16. Refinish all exposed surfaces in trunk and on underbody using quality refinish materials.
17. Apply inner panel rust proofing, such as Mopar # 05093981AA, or equivalent, to the rail inner cavity areas in two applications with a 30-minute flash period between the applications. Pay particular attention to areas which have been welded.
18. Reassemble vehicle and complete repairs.

LEFT SIDE

1 - HOLE
2 - 100 mm (4 in.)
3 - REINFORCEMENT, REAR RAIL INNER, REAR
4 - CUT LOCATION 125 mm (5 in.)

The "Reinforcement, Rear Rail Inner, Rear" (3) ends 100 mm (4 in.) (2) forward of round hole (1) on inner face of "Rail, Rear Inner" - recommended cut location is 125 mm (5 in.) (4) from forward edge of the hole (1).

RIGHT SIDE

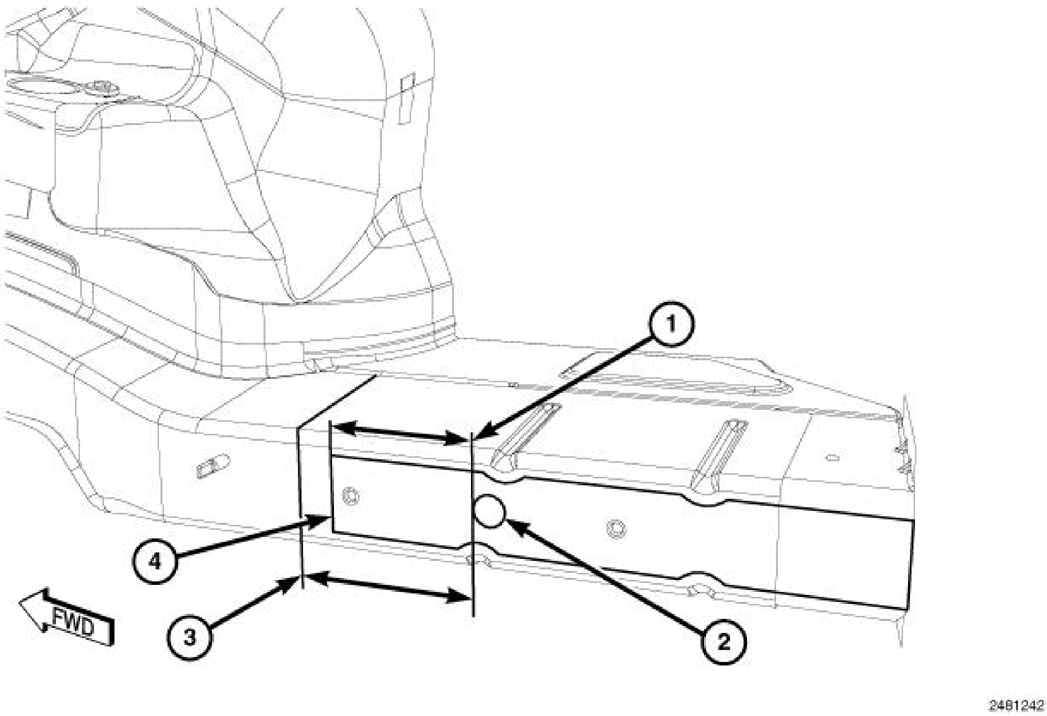

Fig. 44: Right Rear Rail Cut Locations
Courtesy of CHRYSLER GROUP, LLC

1 - 125 mm (5 in.)
2 - HOLE
3 - CUT LOCATION 150 mm (6 in.)
4 - REINFORCEMENT, REAR RAIL INNER, REAR

The "Reinforcement, Rear Rail Inner Rear" (4) ends 125 mm (5 in.) (1) forward of round hole (2) on inner face of "rail, rear inner" - recommended cut location (3) is 150 mm (6 in.) from forward edge of hole (2).

ADDITIONAL INFORMATION

Observe all cautions and warnings per the Chrysler service information . Refer to **FRAME, WARNING**.

Reference the Chrysler weld process chart. Refer to **FRAME, SPECIFICATIONS**.

Butt joint should be metal finished without thinning the base rail material or weldment. This is a cosmetic finishing process to disguise the repair and should have the surface coating (paint) duplicated as well.

Restore corrosion protection when complete with all welding operations.

NOTE: **The rear springs can be lowered with the rear suspension crossmember. Installation of the rear suspension crossmember will require the rear**

springs to be installed after the crossmember is bolted properly into the vehicle.

10. Remove the four bolts (3 and 4).
11. Remove the retainer plates (2).
12. Slowly lower the rear suspension crossmember and guide the brake calipers up through the suspension, following brake hose path. Support the calipers above the crossmember with wire when the crossmember is lowered.

NOTE: **The crossmember isolators can be serviced without removing any additional components.**

13. If necessary, remove the isolators from the crossmember. Refer to **ISOLATOR, REAR CROSSMEMBER, DIFFERENTIAL, REMOVAL**, **ISOLATOR, REAR CROSSMEMBER, FRONT MOUNT, REMOVAL**, **ISOLATOR, REAR CROSSMEMBER, REAR MOUNT, REMOVAL** or **ISOLATOR, REAR CROSSMEMBER, SPRING LINK, REMOVAL**.
14. If necessary, remove the rear stabilizer bar from the crossmember. Refer to **STABILIZER BAR, REAR SUSPENSION, REMOVAL** .
15. If necessary, remove the spring link from the crossmember. Refer to **LINK, SPRING, REMOVAL** .
16. If necessary, remove the toe link from the crossmember. Refer to **LINK, TOE, REMOVAL** .
17. If necessary, remove the camber link from the crossmember. Refer to **LINK, CAMBER, REMOVAL** .
18. If necessary remove the rear knuckle from the crossmember. Refer to **KNUCKLE, REAR, REMOVAL** .

INSTALLATION

INSTALLATION

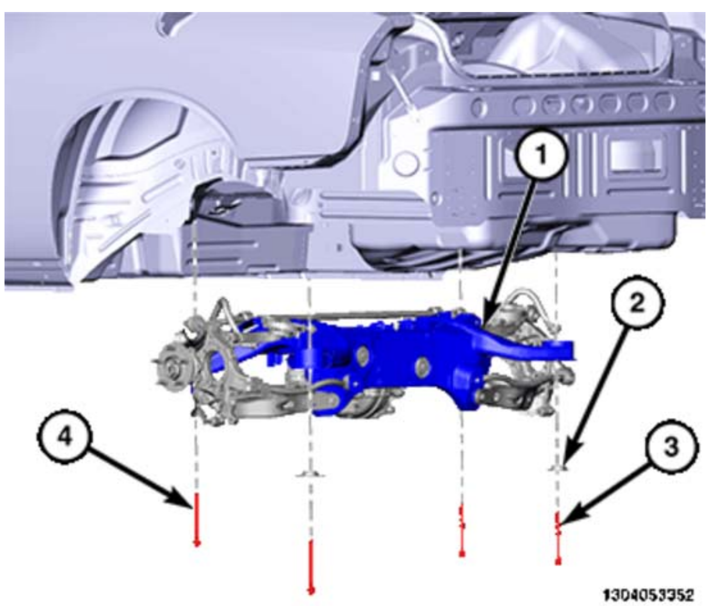

Fig. 60: Rear Suspension Crossmember, Retainer Plates & Bolts

NOTE: **Do not install the rear suspension crossmember with the rear springs attached.**

Install the rear springs after the rear suspension crossmember has been secured properly.

1. Guide the brake calipers up through the suspension and slowly position the rear suspension crossmember (1) into the vehicle. As crossmember is raised, align shocks with pockets in spring links.
2. Loosely install the front bolts (4).
3. Position the retainer plates (2) back into place and loosely install the rear bolts (3).

NOTE: **There are four crossmember mounting bolts. The rear bolts are longer than the front bolts. Do not interchange bolts.**

4. Align the rear suspension crossmember with the reference marks made previously and tighten the rear suspension crossmember to body bolts to the proper torque specification. Refer to **SPECIFICATIONS**.

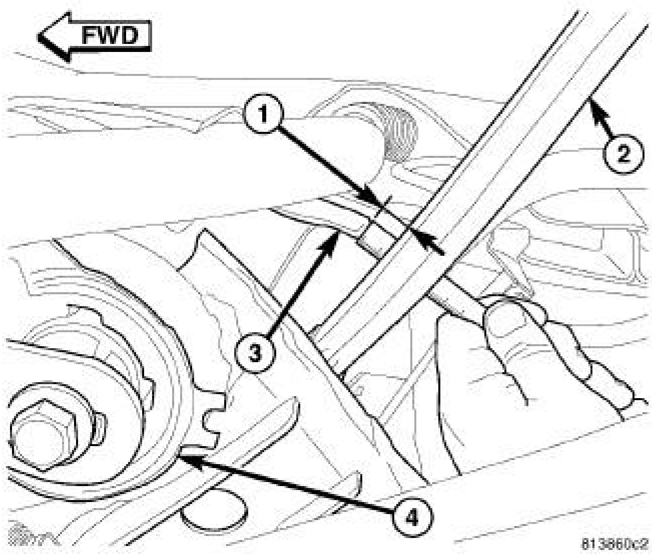

Fig. 61: Measuring Tension Link Clearance
Courtesy of CHRYSLER GROUP, LLC

5. Once mounts are lined up with location marks, on both sides of vehicle, measure distance (1) between the tension link (2) and weld flange (3) on body directly in front of it, just outboard of the front mount bushing (4). **This distance must be at least 12 mm to allow proper clearance for suspension movement.** If distance is less than 12 mm on either side of vehicle, shift that side of rear crossmember directly rearward until distance is 12 mm or greater. To do so, loosen 3 mounting bolts slightly, leaving one on opposite side of shift snugged to pivot off of. Shift crossmember rearward and snug loosened bolts. Remeasure opposite side to be sure it still maintains minimum 12 mm distance.

6. Install the rear springs. Refer to **SPRING(S), INSTALLATION** .
7. Install the lower shock bolt (2) and nut (4) and tighten to the proper torque specification. Refer to **SPECIFICATIONS** .
8. Install the fuel filler tube. Refer to **TUBE, FUEL TANK FILLER, INSTALLATION** .
9. Route the wire harness and connect all wire harness connectors.
10. Install the parking brake cable guide bracket and bolt.

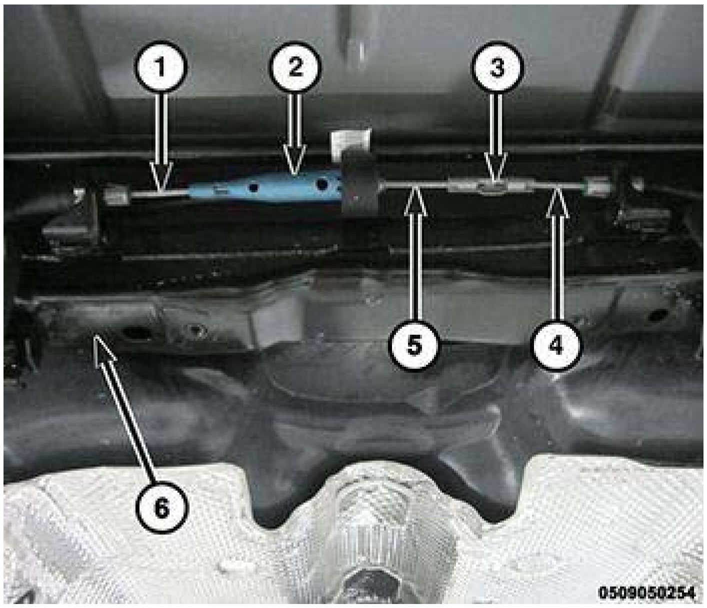

Fig. 63: Cables At Equalizer

11. Connect the rear brake cables back to the front as necessary. Refer to **CABLE, PARKING BRAKE, FRONT, INSTALLATION** or **CABLE, PARKING BRAKE, REAR, INSTALLATION** .

12. Install the rear axle differential. Refer to **INSTALLATION** or **INSTALLATION** .
13. Install the rear brake pads and calipers. Refer to **PADS, BRAKE, INSTALLATION** .
14. Install the muffler. Refer to **MUFFLER, EXHAUST, INSTALLATION** .
15. Install the tire and wheel assembly. Refer to **INSTALLATION** .
16. Check the wheel alignment and adjust if necessary. Refer to **WHEEL ALIGNMENT, STANDARD PROCEDURE** .

NOTE:	**Prior to using (special tool #9520, Remover/Installer, Bushing), lubricate Bolt (1) threads to provide ease of use and promote tool longevity.**
NOTE:	**When installing Thrust Bearing (6), be sure to place hardened side toward Bolt head.**

3. Assemble tools (See following list) over bushing as shown in the illustration.
    - (1) Bolt
    - (2) Nut
    - (3) Washer
    - (4) Receiver (special tool #9520-4, Cup, Receiver)
    - (5) Remover (special tool #9520-3, Remover, Bushing)
    - (6) Thrust Bearing
4. While holding Nut (2) from rotating, **using hand tools** , tighten Bolt (1) until Remover (5) comes in contact with bushing and Receiver (4) sets squarely against crossmember.
5. Continue to tighten Bolt (1), pressing bushing out of crossmember.
6. Remove tools with bushing.

NOTE: **It is important that tapered end (3) of bushing be installed first into forward end of crossmember to ease installation.**

NOTE: **When installing Thrust Bearing (7), be sure to place hardened side toward Bolt head.**

1. Insert tapered end of NEW bushing (3) into forward end of crossmember bushing bore.
2. Assemble tools (See following list) through crossmember and bushing as shown in the illustration.
    - (1) Bolt
    - (2) Disc (special tool #9520-1, Installer Disc)
    - (3) Bushing

- (4) Nut
- (5) Washer
- (6) Installer (special tool #9520-2A, Installer, Bushing)
- (7) Thrust Bearing

3. Insert Installer (6) into end of bushing and Disc (2) into opposite end of crossmember bushing bore.
4. While holding Nut (4) from rotating, tighten Bolt (1) **using hand tools** , pressing bushing into crossmember. Stop when Installer (6) bottoms against bushing bore.
5. Remove tools.
6. Install the rear crossmember. Refer to **CROSSMEMBER, REAR, INSTALLATION** or **CROSSMEMBER, TRANSMISSION, INSTALLATION**.

CAUTION: **Prior to bushing installation, inspect the bushing to make sure it is the correct side bushing for the job. Left side bushings have the travel limiter (1) tipped to the right in relationship to the bushing (4) can flange as shown in the illustration. Right side bushings have the travel limiter (2) tipped to the left in relationship to the bushing (3) can flange as shown in the illustration. Once installed, the travel limiters with face slightly outward from straight-ahead position.**

CAUTION: **It is very important that bushing be installed in same position as original to maintain vehicle ride quality and bushing longevity. That is why bushing, once installed, needs to closely match reference marks applied upon removal of original bushing.**

1. Position bushing on crossmember bushing bore aligning bushing can flange with reference marks applied during removal.

FRONT

DESCRIPTION

NON SRT

Each side of the front suspension includes the following components:

- Hub And Bearing
- Knuckle
- Lower Control Arm
- Strut Assembly
- Stabilizer Bar and Link
- Tension Strut

- Upper Control Arm

SRT

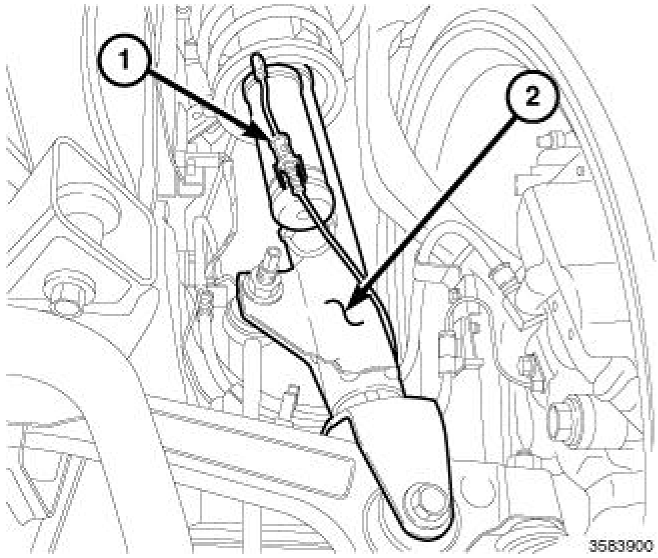

Fig. 1: Front Shock Assembly & Shock Solenoid Assembly
Courtesy of CHRYSLER GROUP, LLC

The SRT front suspension is part of an Active Damping System (ADS). The ADS includes unique shock absorbers, an Active Damping Control Module (ADCM), and three accelerometers that work together to modify the ride of the suspension over varying road conditions.

The Active Damping System (ADS) front shock assembly (2) is similar to a conventional coil over shock with the addition of a shock solenoid assembly (1) mounted on the side of its body with a three wire harness connector attached to it. The ADS shock assembly is serviced the same as a conventional shock absorber, with the addition of disconnecting the ADS harness connector from behind the splash shield.

ARM, LOWER CONTROL

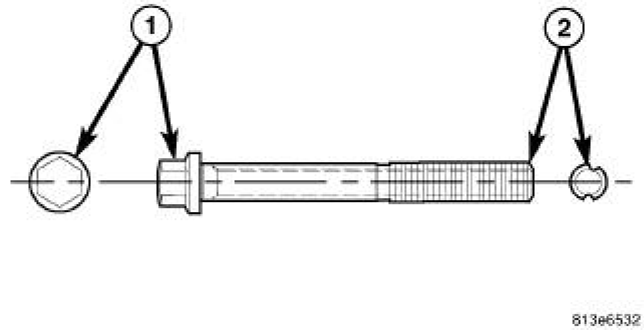
REMOVAL

REMOVAL

NOTE: Removal process is the same for both sides of the vehicle.

1. Raise and support the vehicle. Refer to **HOISTING, STANDARD PROCEDURE** .
2. Remove the tire and wheel assembly. Refer to **REMOVAL** .
3. Remove belly pan. Refer to **BELLY PAN, REMOVAL** and **BELLY PAN, ENGINE, REMOVAL** .
4. Remove the front stabilizer bar. Refer to **STABILIZER BAR, FRONT, REMOVAL**.

NOTE: In the following step, the lower control arm to cradle bolt (3) is accessed through the opening created by removal of the bushing from the stabilizer bar.



[Fig. 2: Wheel Alignment Adjustment Bolt](#)
Courtesy of CHRYSLER GROUP, LLC

CAUTION: If the lower control arm bolt at the engine cradle has a lengthwise grooved shaft (2), it is a special wheel alignment adjustment bolt and the bolt head (1) must not be rotated in the vehicle or damage to the bolt and engine cradle will result. While holding the bolt in place with a wrench, remove the nut, then slide the bolt out of the bushing and cradle taking note of bolt positioning in engine cradle for reassembly purposes. The bolt needs to be installed in the same position as removed to make sure wheel camber and caster return to adjusted position.

[Fig. 3: Lower Control Arm To Engine Cradle Bolt And Nut](#)

5. Remove bolt and nut (1) securing lower control arm to engine cradle. If bolt has a lengthwise grooved shaft (see above CAUTION), remove bolt and nut by holding the bolt in place with a wrench, removing nut, then sliding bolt out of bushing and cradle while taking note of bolt positioning in lower control arm bushing for reassembly purposes.

6. Remove the strut to lower control arm bolt (3).
7. Loosen the lower ball joint to knuckle nut (4). Back nut off until nut is even with end of stud. **Keeping nut on at this location will help keep end of stud from distorting while using Puller in next step.**

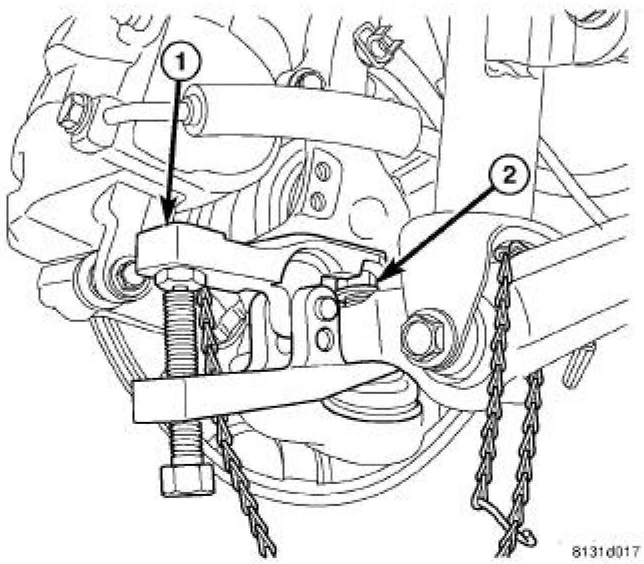

Fig. 5: Using Puller On Lower Control Arm Ball Joint

CAUTION: In following step, use care not to damage ball joint seal boot while sliding into place past seal boot.

8. Using Ball Joint Remover (special tool #9360, Remover, Ball Joint) (1), separate ball joint stud (2) from lower control arm.

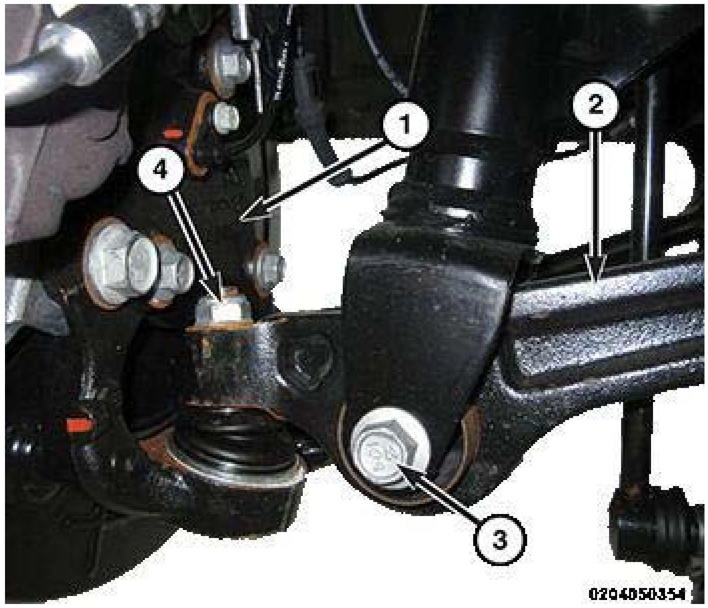

Fig. 6: Knuckle, Lower Control Arm, Strut To Lower Control Arm Bolt & Lower Ball Joint To Knuckle Nut

9. Remove the lower ball joint to knuckle nut (4).
10. Pry knuckle (1) downward and slide ball joint stud out of lower control arm (2). Position knuckle outward, away from lower control arm.
11. Slide lower control arm (2) out of engine cradle and remove from vehicle.

INSTALLATION

INSTALLATION

NOTE: **Installation process is the same for both sides of the vehicle.**

NOTE: **If installing a lower control arm engine cradle bolt that is a wheel alignment adjustment bolt (1) (lengthwise grooved shaft (2)), make sure to install it in the same position which it was in upon removal. For more details on installation of this special bolt. Refer to WHEEL ALIGNMENT, STANDARD PROCEDURE.**

1. Slide lower control arm into position in engine cradle.
2. Install the lower control arm to cradle bolt and nut (1), but **do not tighten at this time** .

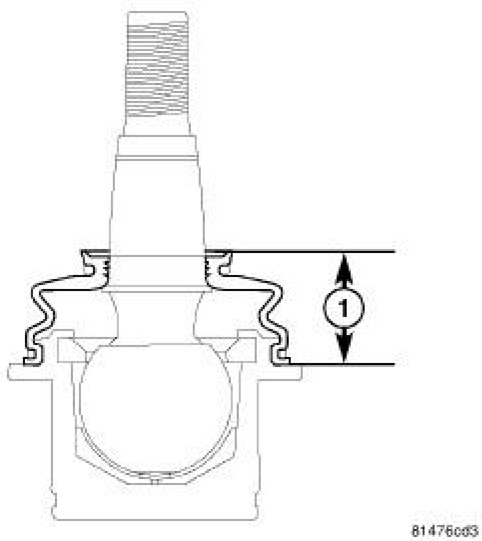

Fig. 9: Ball Joint Seal Boot Height
Courtesy of CHRYSLER GROUP, LLC

CAUTION: **Before installing knuckle on lower control arm, measure height of ball joint seal boot (1) mounted on knuckle. If seal boot height is above 25.5 mm, any air inside seal boot must be expelled. To do so, follow these steps.**

- **Tip ball joint stud completely to one side.**
- **Using thumb and index finger, gently squeeze seal boot together at center expelling any air. Do not allow grease to be release.**

- **Push down very top of seal boot.**
- **Return ball joint stud to original "centered" position.**
- **Measure ball joint seal boot height (1) making sure it is within specification.**
- **Wipe any grease from ball joint stud.**

3. Pull knuckle (1) downward and position the lower control arm (2) over ball joint stud. Release knuckle, guiding stud into lower control arm. Install a **NEW** lower ball joint to knuckle nut (4). Tighten lower ball joint to knuckle nut by holding ball joint stud with a hex wrench while turning nut with a wrench. Tighten to the proper specification. Refer to **FRONT, SPECIFICATIONS**.
4. Install the strut to lower control arm bolt (3). **Do not tighten bolt at this time.**
5. Install the tire and wheel assembly. Refer to **INSTALLATION** .
6. Remove the support and lower the vehicle.

CAUTION: Because stabilizer bar is disconnected at cradle it is important to use extra care while moving vehicle to alignment rack/drive-on lift.

7. Position vehicle on an alignment rack/drive-on lift.
8. Tighten the strut to lower control arm bolt (3) to the proper specification. Refer to **FRONT, SPECIFICATIONS**.

REMOVAL

REMOVAL

NOTE: Removal process is the same for both sides of the vehicle.

1. If removing left upper control arm, remove and reposition engine coolant recovery container. Refer to **BOTTLE, PRESSURIZED COOLANT, REMOVAL** .
2. If removing right upper control arm, remove and reposition supercharger coolant recovery container. Refer to **RESERVOIR, COOLANT, REMOVAL** .
3. If removing right upper control arm, remove the power distribution center (PDC) from mount and reposition.

8. If installing left upper control arm, install engine coolant recovery container. Refer to **BOTTLE, PRESSURIZED COOLANT, INSTALLATION** .
9. If installing right upper control arm, install the supercharger coolant recovery container. Refer to **RESERVOIR, COOLANT, INSTALLATION** .
10. If installing right upper control arm, install the power distribution center.

BALL JOINT, SUSPENSION, LOWER

DESCRIPTION

DESCRIPTION

There are two lower ball joints on this vehicle. One for the lower control arm and the other for the tension strut. The ball joint for the lower control arm is pressed into the knuckle and the ball joint for the tension strut is part of the tension strut. The ball joints are both "sealed for life" components and cannot be maintenance lubricated. **No attempt should ever be made to add any lubrication to these ball joints.**

The ball joint for the lower control arm is a ball joint and seal boot cartridge type and can be replaced as a separate component of the knuckle. The boot cannot be serviced separately. To service this ball joint, refer to **KNUCKLE, STEERING, DISASSEMBLY**.

Neither the ball joint, nor the seal boot for the tension strut can be serviced as a separate component. The entire tension strut must be replaced if either are damaged.

The ball joint connection to the lower control arm and the ball joint connection at the knuckle is achieved by an interference fit created by the tapered stud of the ball joint and a tapered hole in the steering knuckle. The ball joint stud is retained in the steering knuckle using a locking nut.

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - LOWER BALL JOINT

1. Raise vehicle on a drive-on hoist.

NOTE: If a drive-on hoist is not available, use wooden blocks with jack stands to support the lower control arm in the ball joint area. Place the jack stands appropriately and lower the hoist placing weight on the lower control arm. The lower control arms should now be supporting the vehicle weight.

2. Using a jack, lift the front end off the hoist and position a wooden block underneath lower control arm supporting that portion of the vehicles weight.
3. Remove tire and wheel assembly. Refer to **REMOVAL** .
4. Attach a dial indicator as follows:
   a. Tension Strut - Attach a dial indicator to base of tension strut, then align dial indicator's contact pointer with direction of stud axis and touch machined flat on knuckle near ball joint. Zero dial indicator.
   b. Lower Control Arm - Attach a dial indicator to base of lower control arm, then align dial indicator's contact pointer with direction of stud axis and touch machined flat on knuckle near ball joint. Zero dial indicator.

NOTE: Use care when applying the load to the knuckle so as to not damage components of the suspension.

5. Insert a pry bar and rest it against lower control arm or tension strut (depending on which is being tested) and use lever principle to push knuckle upward until dial indicator no longer moves.
6. Record any ball joint movement. If movement in the lower control arm exceeds 1.5 mm (.059 in.), the ball joint is faulty.
7. If the ball joint for the lower control arm needs replaced, it can be serviced separately. Refer to **KNUCKLE, STEERING, DISASSEMBLY**.
8. If the tension strut ball joint needs replaced, the entire tension strut needs to be replaced. Refer to **STRUT, TENSION, REMOVAL**.

REMOVAL

REMOVAL

To service the lower ball joint for the lower control arm, the knuckle must be removed from the vehicle, then the ball joint can be removed. Refer to **KNUCKLE, STEERING, DISASSEMBLY**.

INSTALLATION

INSTALLATION

To install the ball joint for the lower control arm. Refer to **KNUCKLE, STEERING, ASSEMBLY**.

BALL JOINT, SUSPENSION, UPPER

DESCRIPTION

DESCRIPTION

The upper ball joint is pressed into the upper control arm. The ball joint is a "sealed for life" component and cannot be maintenance lubricated. This ball joint is lubricated for life at the time of assembly. **No attempt should be made to ever add any lubrication to this ball joint.**

Neither the upper ball joint, nor the seal boot can be serviced as a separate component. The entire upper control arm must be replaced if either are damaged.

The ball joint connection at the knuckle is achieved by an interference fit created by the tapered stud of the ball joint and a tapered hole in the steering knuckle. The ball joint stud is retained in the steering knuckle using a locking nut.

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - UPPER BALL JOINT

1. Raise vehicle on a drive-on hoist.

NOTE: **If a drive-on hoist is not available, use wooden blocks with jack stands to support the lower control arm in the ball joint area. Place the jack stands appropriately and lower the hoist placing weight on the lower control arm. The lower control arms should now be supporting the vehicle weight.**

2. Using a jack, lift the front end off the hoist and position a wooden block underneath lower control arm supporting that corner of the vehicles weight.
3. Remove the tire and wheel assembly. Refer to **REMOVAL** .
4. Attach a dial indicator to body of upper control arm, then align dial indicator's contact pointer with direction of stud axis and touch machined flat on end of knuckle near ball joint. Zero dial indicator.

NOTE: **Use care when applying the load to the knuckle so as to not damage components of suspension.**

5. Insert a pry bar and rest it against bottom of upper control arm and use lever principle to push arm upward until dial indicator no longer moves.
6. Record any ball joint movement. If movement in the control arm exceeds 1.5 mm (.059 in.), the ball joint is faulty.
7. If the ball joint needs replaced, the entire upper control arm needs to be replaced. Refer to **ARM, UPPER**

HUB AND BEARING

DESCRIPTION

DESCRIPTION

Fig. 19: Hub & Bearing
Courtesy of CHRYSLER GROUP, LLC

The front wheel bearing and wheel hub of this vehicle are a one-piece sealed unit or hub and bearing unit type assembly.

On Rear-Wheel Drive SRT8 vehicles, the hub and bearing is mounted to the center of the knuckle using three bolts.

All front hub and bearings have five wheel mounting studs on the hub flange for mounting the wheel to the vehicle. The wheel mounting studs are the only replaceable components of the hub and bearing. Otherwise, the hub and bearing is serviced only as a complete assembly.

A magnetic encoder for the wheel speed sensor is pressed onto the hub and bearing.

DIAGNOSIS AND TESTING

DIAGNOSIS AND TESTING - HUB BEARING - NOISE

NOTE: **The wheel bearing is designed to last for the life of the vehicle and requires no type of periodic maintenance. If it becomes necessary to replace a faulty bearing, do not replace in pairs unless parts manual specifically states to do so.**

Bearings will produce noise if worn or damaged. The noise will generally change when the bearings are loaded. A road test of the vehicle is normally required to determine if there is a bearing noise, or if it is some other component. To assist in finding the location, the following procedure, together with the **DIAGNOSTIC TABLE** , should help determine if a bearing is causing the noise, and if so which one. Keep in mind that

bearing noises are not typically intermittent. If a particular vehicle road test maneuver results in noise only part of the time, it is not likely a faulty bearing.

NOTE: **Damaged bearing seals and the resulting excessive grease loss may also require bearing replacement. Moderate grease seepage from the bearing is considered normal and should not require replacement of the wheel bearing. To diagnose the hub, measure hub runout. Refer to ROTOR, BRAKE, DIAGNOSIS AND TESTING .**

DIAGNOSTIC PROCEDURE:

1. Perform a drive evaluation. Find a smooth level road surface void of traffic or obstructions. Turn off any accessories which may cause background noise. Evaluate for noise at 50 km/h (30 mph) and 100 km/h (60 mph) and with vehicle in neutral to eliminate potential drivetrain noises. With vehicle at a constant speed, steer back and forth to left and right. This will load and unload the bearings and may change the noise level. When bearing damage is slight, the noise is sometimes noticeable at lower speeds and at other times is more noticeable at higher speeds.
2. Drive evaluation results: Did the noise increase when turning right which may indicate a problem with the left bearing? Did the noise increase when turning left which may indicate a problem with the right bearing?
3. Put vehicle up on hoist. Grab the tire by pushing in on the top center and pulling out on the bottom center to check for excessive movement in the bearing.
4. Check for potential rubbing on rotating components, such as rotor splash shields, heat shields touching propshaft or halfshaft, wheel well liners contacting tire, wheel cover on wheel, etc. Any cyclic noise (once per wheel revolution for example) is not a wheel bearing fault.
5. Remove the wheel and tire assembly, disc brake caliper and brake rotor. Refer to **ROTOR, BRAKE, REMOVAL** .
6. Rotate the wheel hub, checking for resistance or roughness.
7. Any roughness or resistance to rotation may indicate dirt intrusion or a failed hub bearing. If the bearing exhibits any of these conditions, the hub & bearing will require replacement. Do not attempt to disassemble the bearing for repair.
8. Rotate the wheel hub, utilize Chassis Ears (or stethoscope) to check for noise.
9. If none of the above checks indicate a bearing failure, refer to the **DIAGNOSTIC TABLE** for other possible causes.

SENSOR, ACTIVE DAMPING

DESCRIPTION

DESCRIPTION

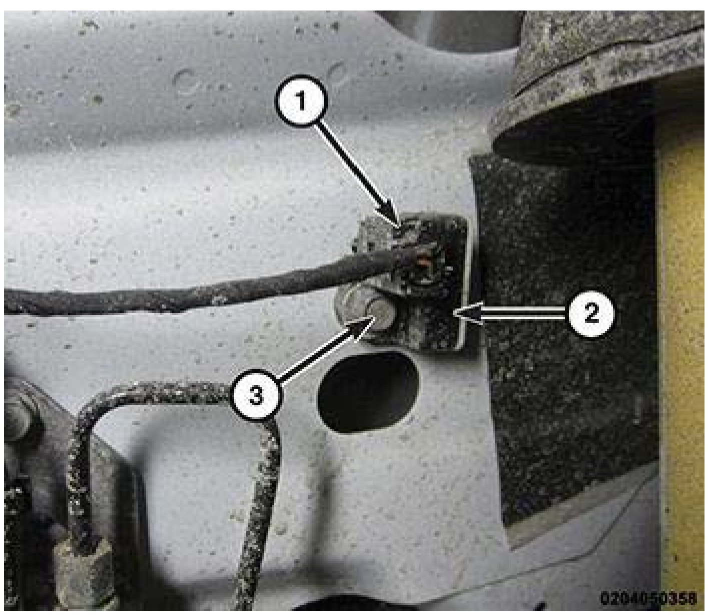

Fig. 37: Damping Sensor, Connector & Bolt
Courtesy of CHRYSLER GROUP, LLC

NOTE: **Left front sensor shown in illustration.**

There are three active damping sensors (2). The front sensors are located in each front wheel well next to the brake line junction. The rear sensor is mounted in the right rear wheel well on the shock tower. The sensors are 3 wire, 5V reference sensors wired directly to the Active Damping Control Module (ADCM).

OPERATION

OPERATION

The Active Damping Control Module (ADCM) uses the CAN bus to communicate with multiple modules. The ADCM has the following inputs: Vehicle Speed, Steering Angle Sensor (SAS) position, Throttle Position Sensor (TPS), Active Damping System (ADS) Switch, and three active damping sensors.

There are two operating modes of the ADS, Auto and Sport. At each ignition key on cycle, the vehicle defaults to Auto mode. When Sport mode is selected, the suspension has unique handling characteristics.

The Active Damping Control Module (ADCM) controls the suspension and ride for the SRT version of this vehicle by adjusting the rebound and jounce of the shock assemblies using the above information and predetermined settings for maximum vehicle control. The shock absorbers are unique to the ADS. Each shock absorber has a valving unit that is external, but still part of the shock absorber. Inside each valving unit are two solenoids that control the damping valves to alter the ride of the vehicle. The shocks are replaced as an assembly, they cannot be disassembled for repair.

Additionally, there are three active damping sensors, two in the front of the vehicle and one in the rear. These sensors measure the plane of the vehicle.

DISASSEMBLY

DISASSEMBLY

Fig. 47: Identifying Pliers On Chrome Machined Surface Of Shock/Strut Rod
Courtesy of CHRYSLER GROUP, LLC

CAUTION: Do not use any type of pliers on the chrome machined surface of shock/strut rod to assist in the disassembly/assembly of shocks or struts. Use only tools designed to hold the shock/strut rod stationary when servicing shock or strut components.

The shock assembly must be removed from vehicle for it to be disassembled and assembled.

For shock assembly disassembly and assembly, use of shock Spring Compressor, Mopar Service Equipment (MSE) tool W-7200, or equivalent, is recommended to compress coil spring. Follow manufacturer's instructions closely.

WARNING: Do not remove shock shaft nut before coil spring is compressed. Coil spring is held under pressure and must be compressed, removing spring tension from upper and lower mounts, before shock removal.

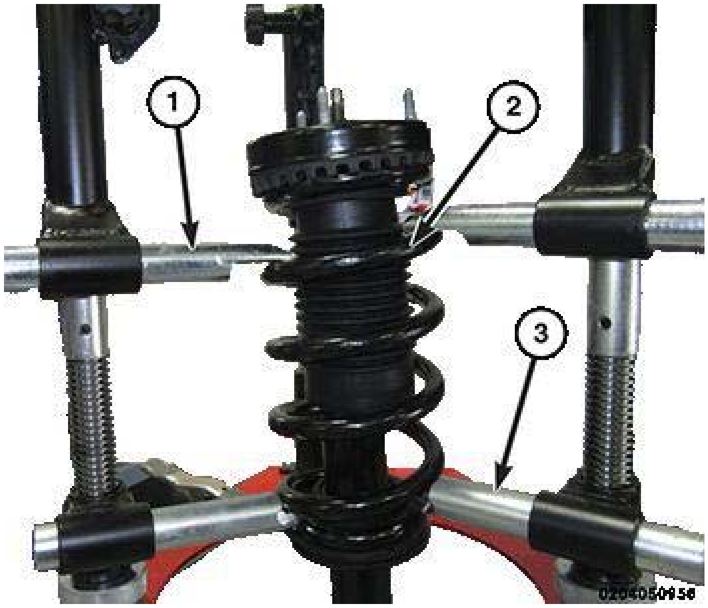

Fig. 48: Compressor Hooks & Coil Spring
Courtesy of CHRYSLER GROUP, LLC

1. Position shock assembly coil spring (2) on hooks (1, 3) of the compressor following manufacturers instructions. Install clamp securing shock to the upper and lower spring coil. To ease installation, rotate shock as necessary positioning shock in compressor so that upper spring coil ends (step in upper mount) at straight outward position from compressor.
2. Compress coil spring (2) until all spring tension is removed from upper mount.

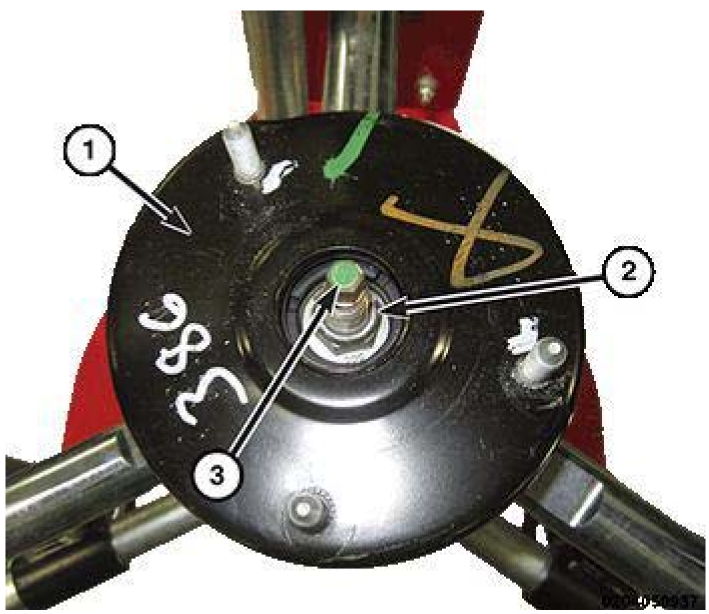

Fig. 49: Removing/Installing Shock Absorber Shaft Nut

3. Using the appropriate tool, remove the shock absorber shaft nut (3).
4. Remove clamp from bottom of coil spring and remove shock and lower isolator out through bottom of coil spring.
5. Remove upper mount (1) from shock shaft and coil spring if replaced is necessary.

NOTE: **Prior to removing spring from compressor, note location of lower spring coil end in relationship to compressor to ease assembly of components later.**

6. Back off compressor drive, releasing tension from coil spring. Push back compressor upper hooks and remove coil spring from compressor.

7. Remove jounce bumper from shock shaft by pulling straight up and off.
8. Remove lower isolator (4) from shock body by pulling straight up and off shock shaft.
9. Inspect shock assembly components for following and replace as necessary:

- Inspect shock (3) for any condition of shaft binding over full stroke of shaft.
- Inspect upper mount (1) for cracks and distortion and its retaining studs for any sign of damage.
- Inspect upper spring isolator (1) for severe deterioration.
- Inspect lower spring isolator (4) for severe deterioration.
- Inspect dust shield for tears and deterioration.
- Inspect coil spring (2) for cracks in the coating and corrosion.
- Inspect jounce bumper for cracks and signs of deterioration.

CAUTION: Do not use any type of pliers on the chrome machined surface of shock/strut rod to assist in the disassembly/assembly of shocks or struts. Use only tools designed to hold the shock/strut rod stationary when servicing shock or strut components.

CAUTION: Use care not to damage coil spring coating during spring assembly. Damage to coating will jeopardize its corrosion protection.

NOTE: Left and right springs must not be interchanged.

1. Place coil spring (2) **(part number tag end upward)** in compressor lower hooks following manufacturers instructions. To ease shock reassembly, rotate coil spring around until upper coil ends at straight outward position from compressor. Proper orientation of spring to upper mount (once installed) is necessary.
2. Position compressor upper hooks over coil spring following manufacturers instructions.
3. Compress coil spring far enough to allow shock installation.
